1 About This Document

This document is intended as an introduction to user commands, a guide to creating and implementing new user commands and a summary of the predefined user commands supplied with Dyalog.

1.1 Audience

It is assumed that the reader has a reasonable understanding of Dyalog.

For information on the resources available to help develop your Dyalog knowledge, see <http://www.dyalog.com/introduction.htm>.

1.2 Conventions

Unless explicitly stated otherwise, all examples in Dyalog documentation assume that `⎕IO` and `⎕ML` are both 1.

Various icons are used in this document to emphasise specific material.

General note icons, and the type of material that they are used to emphasise, include:

Hints, tips, best practice and recommendations from Dyalog Ltd.

Information note highlighting material of particular significance or relevance.

Legacy information pertaining to behaviour in earlier releases of Dyalog or to functionality that still exists but has been superseded and is no longer recommended.

Warnings about actions that can impact the behaviour of Dyalog or have unforeseen consequences.

Although the Dyalog programming language is identical on all platforms, differences do exist in the way some functionality is implemented and in the tools and interfaces that are available. A full list of the platforms on which Dyalog version 17.0 is supported is available at www.dyalog.com/dyalog/current-platforms.htm. Within this document, differences in behaviour between operating systems are identified with the following icons (representing macOS, Linux, UNIX and Microsoft Windows respectively):

2 Introduction

User commands are tools that are available at any time, in any workspace, as extensions to the Dyalog development environment. The text-based implementation of user commands allows development tools to be easily shared between users, and the ability to create custom user commands in addition to the predefined user commands that are supplied with Dyalog means that it is simple to write utility tools for your environment that can be easily issued to an entire development team.

User commands are entered in an APL Session by starting an input line with a `]` character, for example:

```
      ]ToHex 250+ι5
FB  FC  FD  FE  FF
```

A section of the APL Wiki is devoted to sharing custom user commands (see <https://aplwiki.com/CategoryDyalogUserCommands>).

2.1 Cache File

The first time that you start a Dyalog Session after installing/updating Dyalog, a cache file is created comprising the name of each of the user commands and the file in which it is defined. This can take a few seconds. If any of the files that contain user commands are altered or a new file containing user commands is created, then the cache file is rebuilt:

- the next time a Dyalog Session is started.
- when the `]UReset` user command is run (forces an in-Session recache).
- if a user attempts to run (or get help about) a user command that is not in the cache.

The cache file is also rebuilt if a user command is called after updating the `cmddir` global parameter (using the `]Settings` user command – see *Section 5.10.9*).

By default, the cache file is located in:
Documents\Dyalog APL <version> Files\UserCommand20.cache

 By default, the cache file is located in:
\$HOME/.dyalog/UserCommand20.cache

 By default, the cache file is located in:
Users/<name>/.dyalog/UserCommand20.cache

The name and location of the cache file can be changed from its default by setting the *UCMDCACHEFILE* environment variable.

2.1.1 Defining the UCMDCACHEFILE Environment Variable

The name and location of the cache file can be changed from its default by setting the *UCMDCACHEFILE* environment variable.

Defining an environment variable is operating system-specific.

To define the UCMDCACHEFILE environment variable on Microsoft Windows (permanent method)

1. Open the **Control Panel** and double-click on the **System** icon.
The **System** window is displayed.
 2. In the **Control Panel Home** pane, click **Advanced system settings**.
The **System Properties** window is displayed.
 3. Navigate to the **Advanced** tab of the **System Properties** window.
 4. Click **Environment Variables....**
The **Environment Variables** dialog box is displayed.
 5. In the **User variables for <user>** pane, click **New....**
The **New User Variable** dialog box is displayed.
 6. In the **Variable name** field, enter UCMDCACHEFILE.
 7. In the **Variable value** field, enter **<full path>\<cache file name>** of the user commands cache file.
 8. Click **OK** to create the new environment variable and exit the **New User Variable** dialog box.
 9. Click **OK** to exit the **Environment Variables** dialog box.
 10. Click **OK** to exit the **System Properties** window.
 11. Close the **System** window.
-

To define the UCMDCACHEFILE environment variable on Microsoft Windows (temporary method – for session duration only)

1. Open the **cmd.exe** application.
2. At the command prompt, enter:

```
dyalog.exe UCMDCACHEFILE=[UCMDCACHEFILE]
```

where [UCMDCACHEFILE] is the new <full path>\<cache file name> of the user commands cache file.

To define the UCMDCACHEFILE environment variable on UNIX (temporary method – for session duration only)

1. Open a shell.
2. At the command prompt, enter:

```
UCMDCACHEFILE=[UCMDCACHEFILE] dyalog
```

where [UCMDCACHEFILE] is the new <full path>\<cache file name> of the user commands cache file.

To define the UCMDCACHEFILE environment variable on macOS (temporary method – for session duration only)

1. Open the **\$HOME/.dyalog/dyalog.config** file in your preferred text editor.
2. Add the following:

```
UCMDCACHEFILE=[UCMDCACHEFILE]
```

where [UCMDCACHEFILE] is the new <full path>\<cache file name> of the user commands cache file.

3 Using User Commands

This chapter introduces some of the concepts that underpin user commands in Dyalog.

3.1 Installation

A set of predefined user commands is installed automatically with Dyalog.

Updates to the set of predefined user commands can be downloaded from <https://www.dyalog.com/tools/user-commands.htm>.

3.2 Directory Structure

The `[DYALOG]\SALT\spice` directory contains the predefined user commands that are installed with Dyalog.

The `spice` directory can only be moved to a different location by moving its parent `SALT` directory and setting the `SALT` environment variable accordingly. For information on moving the `SALT` directory and setting the environment variable, see the *SALT User Guide*.

Although the `spice` directory can be moved, it must always remain directly beneath the `SALT` directory and must not be renamed.

3.3 Implementation

When an input line in a Session starts with a `]` character, Dyalog looks for the function `SE . UCMD`:

- if this function exists, then it is called with the rest of the input line as the right argument and a reference to calling space as the left argument.
- if this function does not exist, then user commands are disabled.

This implementation means that application code can invoke user commands by calling `SE . UCMD` directly.

Dyalog Ltd reserves the right to change the implementation of the user command framework.

EXAMPLE

The following command is entered while in a namespace:

```
]<ucmd> -myModifier=value
```

Dyalog's interpreter preserves this exactly and makes the following call:

```
[THIS [SE.UCMD '<ucmd> -myModifier=value']
```

`SE . UCMD` converts this into a call to the user command framework; the functions defined for `<ucmd>` are actioned with the `-myModifier` modifier applied with a value of `value` and the result is displayed in the Session.

EXAMPLE

The result of `<ucmd>` is assigned to a variable called `<variable>`:

```
]<variable><<ucmd> -myModifier=value
```

Dyalog's interpreter preserves this exactly and makes the following call:

```
[THIS [SE.UCMD '<variable><<ucmd> -myModifier=value']
```

`SE . UCMD` converts this into a call to the user command framework; the functions defined for `<ucmd>` are actioned with the `-myModifier` modifier applied with a value of `value` and the result is assigned to `<variable>`.

If `<variable>` was not included then the result of `<ucmd>` would be discarded.

3.3.1 Customising the Implementation

Although it is possible to implement a custom user command system by redefining `SE . UCMD`, Dyalog Ltd does not recommend this approach – adhering to the user command framework supplied with Dyalog promotes a single, consistent, format that enables all custom user commands to be shared between Dyalog Sessions.

3.4 File Format

Each user command comprises a script containing a single namespace object (for more information on scripted files, including declaration statements and permitted constructs, see the *Dyalog Programming Reference Guide*) and must be stored as files with the **.dyalog** extension.

If an extension is not specified when using user commands to save a script file, then **.dyalog** is automatically appended.

By default, double-clicking on a **.dyalog** file opens that file using the standalone editor.

Files with the **.dyalog** extension are Unicode text files. This means that they can store any text that uses Unicode characters. This format includes most of the world's languages and the Dyalog character set, and is supported by many software applications. By using text files as a storage mechanism, user commands and other tools written using Dyalog can be combined with industry-standard tools for source code management.

3.5 Groups

User commands with common features can be grouped together under a single name. These groups have no effect on the functionality of the individual user commands but enable related user commands to be gathered together for ease of reference and provide a means of sorting and classifying user commands that can be very useful as the number of user commands increases.

User command names must be unique within a group but do not have to be unique across all groups. This means that groups allow a systematic naming convention for user commands that perform similar functions on different types of APL object, for example, the predefined user command **]FILE.Compare** compares two files, **]ARRAY.Compare** compares two arrays and **]FN.Compare** compares two functions.

Although a user command can have the same name as its group (or another group), Dyalog Ltd does not recommend this as it can introduce ambiguity to a user reading the code.

When running (or asking for help on) a user command, the group name can be prefixed to the user command name, separated by a **.** character; this group name prefix is mandatory if the user command name is not unique across all groups.

Every user command must be in a group, and every group must comprise at least one user command.

3.6 Syntax in Dyalog Sessions

User commands are entered in a Dyalog Session with a preceding right bracket. The basic syntax is as follows:

- to run a user command:]<ucmd>...
- to display general help information:]
- to list all user commands in their groups (without descriptions):]?
- to list all user commands in their groups (with descriptions):]??
- to list all the available commands in a specific group:]<groupname> -?
- to display brief information for a user command:]<ucmd> -?
- to display detailed information for a user command:]<ucmd> -??
- to display additional information for a user command:]<ucmd> -???
- to list all the available commands defined in **.dyalog** files in a specific directory:]<full path to directory>/<directory name> -?
- to list all user commands or groups that match pattern X*YZ*(* is a wildcard):]X*YZ* -?
- to assign the result of a command to a variable:]<var>+<ucmd>...
- to discard the result of a command:]-<ucmd>...

The names of user commands and groups are not case-sensitive although their arguments, modifiers and modifier values might be. The convention used in this document is that group names are shown in uppercase and user command names are shown in upper CamelCase.

3.6.1 Requesting Additional Information

Help can be requested in a Dyalog Session using the following syntax:

- for general help on user commands:]
- for help on a specific user command:]<ucmd> -? or]Help]<ucmd>
- for more detailed help on a specific user command:]<ucmd> -??

For a specific user command, the information that is returned is dependent on the level of help requested. This level is defined to be 1 less than the number of ? characters entered after the - character; for example,]<ucmd> -?? returns the information defined for

level 1 of the `<ucmd>` user command. The number of levels of help available depends on a user command's definition (for information on defining multiple levels of help in custom user commands, see *Section 4.4.1*).

3.7 Running User Commands

User commands are run with the following syntax:

```
]<ucmd> <-modifiers/arguments>
```

For information on the precise syntax for each user command, the arguments that can be supplied to it and the modifiers that it can take, enter `]<ucmd> -?` or `]Help]<ucmd>` in a Dyalog Session.

When running a user command, the name of that command must be entered in full.

Dyalog's auto-complete functionality means that any user commands that match the entered string are presented as selectable options, making it easy to correctly specify the requisite user command. (Auto-completion is not available in the TTY version of Dyalog.)

The names of user commands are not case-sensitive although their arguments, modifiers and modifier values might be.

3.7.1 Arguments

Some user commands can accept (or require) one or more arguments. To see a list of the possible arguments for a user command, enter `]<ucmd> -?` or `]Help]<ucmd>` in a Dyalog Session.

For example, the behaviour of the user command `]CD` depends on the argument supplied when calling it. If it is run with no argument, then it returns the current working directory – this is equivalent to entering `cd` on the command line of a Microsoft Windows operating system or `pwd` in UNIX. However, if a single argument specifying the full path to a directory is supplied, then the user command changes the current working directory to be the one specified by the argument.

3.7.2 Modifiers and Modifier Values

The default behaviour of a user command can be altered through the application of *modifiers* (instructions that the command should change its default behaviour).

Modifiers must be prefixed with the `-` character and are separated from any associated modifier values with the `=` character, for example, `-version=3` or `-format=APL`. A modifier that does not accept a modifier value but can only be present or absent is sometimes referred to as a flag or a switch, for example, `-protect`.

When running a user command with a specified modifier, the name of the modifier does not always need to be entered in full as long as enough of the modifier's name is entered for it to be interpreted unambiguously. For example, if a user command has a modifier called `-version` and does not have any other modifiers starting with the letter `v` then the function can be successfully called with modifiers `-version`, `-vers`, `-v`, and so on.

Multiple modifiers can be included in a user command call – in this situation they must be separated by a space character. The order in which they are specified is irrelevant.

4 Creating User Commands

When an instruction is called repeatedly it can improve efficiency to have that instruction in a script file. The user command framework provides a very efficient mechanism for doing this, allowing a user to create and update instructions without the necessity of maintaining a workspace. Unlike a workspace, user commands do not need to be loaded into each Session. In addition, their text-based implementation makes them easy to store in a repository and share between users.

This chapter describes the syntax, rules and conventions governing the creation of custom user commands.

4.1 Basic Definition

A new user command can be defined in one of the following ways:

- in a text file (for example, using Microsoft Notepad) and then saved as a **.dyalog** file
- in a Dyalog Session and saved as a **.dyalog** file using the `]Save` user command.
- in a Dyalog Session using the `]UNew` user command.

Once in the appropriate directory (see *Section 4.7*), the new user command can be run from the Dyalog Session.

The script for Dyalog's predefined user commands can be a useful starting point when creating a new user command. The location of an existing user command's script can be found in the following ways:

- `]UVersion <ucmd>` returns the script location for the specified user command
- `]ULoad <ucmd>` loads the script for the specified user command into the active workspace and returns the script location.
- `]<ucmd> -?` returns the script location for the specified user command if `]UDebug` is on.

User commands are defined by three specific APL functions (along with any additional functions needed for the particular purpose of the user command). The three functions must be called:

- `List` – for information on the `List` function, see *Section 4.2*.
- `Run` – for information on the `Run` function, see *Section 4.3*.
- `Help` – for information on the `Help` function, see *Section 4.4*.

These functions are wrapped together in a namespace (the order in which the functions are specified within the namespace is not important). A single namespace can host multiple user commands, but must only have one instance of each of the three functions irrespective of how many user commands it contains. (Although a class can be used instead of a namespace, a namespace is the recommended approach.)

See *Appendix A* for some sample user commands that demonstrate the use of multiple levels of help and parsing user command lines. See *Appendix B* for some examples of user commands wrapped in a namespace – these show how the `List`, `Help` and `Run` functions are defined.

4.2 The List Function

The `List` function informs the user command framework about the command being defined, enabling it to display a summary of the command when requested to list all available commands (`[] -?`), optionally with descriptions (`[] -??`).

The `List` function is niladic and returns one namespace for each user command defined within it. Each namespace contains four variables:

- `Desc` – a summary of the user command's functionality
- `Name` – the name of the user command (see *Section 4.2.1*)
- `Group` – the name of the group to which the command belongs (see *Section 4.2.2*)
- `Parse` – parsing information for the framework (see *Section 4.2.3*)

4.2.1 Name

User commands must have unique names within a group (names can be replicated across different groups if required). They must be valid APL identifier names (for more information on legal names, see the *Dyalog Programming Reference Guide*).

Modifiers must have unique names within the user command but do not have to be unique within the superset of user commands. Modifier names are case-sensitive.

The names of user commands and modifiers cannot contain space characters.

When naming a modifier, avoid the names *Arguments*, *Delim*, *Propagate*, *SwD* and *Switch* as these names are used by the parser.

4.2.2 Group

Every user command must be a member of a group (but can only be a member of one group). In addition:

- the user commands for a single group do not all need to be defined within a single namespace/**.dyalog** file
- a single namespace/**.dyalog** file can include user commands for several different groups
- user command names must be unique within a group but do not have to be unique across all groups (however, custom user commands should not be given the same name as any of the predefined user commands within the SALT group).

Although it is possible to add a custom user command to one of the predefined user command groups, Dyalog Ltd recommends that this is avoided as there could be unforeseen consequences (especially with the SALT and UCMD groups).

4.2.3 Parse

If the `Parse` variable for a user command is empty, then the `Run` function's second argument will comprise everything following the command name. By setting the `Parse` variable to non-empty values, the user command framework is able to handle arguments and modifiers. For more information on modifiers and modifier values, see *Section 4.5*. For more information on arguments, see *Section 4.6*.

The following general rules apply when processing a call to a user command:

- user commands take 0 or more arguments and by 0 or more modifiers
- individual arguments and modifiers are separated by space characters
- arguments and modifiers can be specified in any order
- arguments can be optional or mandatory
- modifiers are identified by a preceding `-` character
- modifier values are identified by a preceding `=` character
- modifier names are case-sensitive
- individual arguments and modifier values can be delimited by single or double quotes to allow leading/trailing/internal space characters or to allow arguments that have a leading `-` character.

The user command framework verifies that these rules have been adhered to before creating a new namespace. It then populates this namespace with a variable called `Arguments` (containing all the arguments) and a variable for each of the modifiers with names matching those of the modifiers. Other manipulation tools are also added to the namespace, for example, the `Switch` function – see *Section 4.5.1*. This namespace is passed to the `Run` function (see *Section 4.3*) as its second argument.

If the `Parse` variable defined in a user command's `List` function is empty, then the user command will accept anything; the entire string is the argument.

If the `Parse` variable defined in a user command's `List` function is not empty, then it must describe the number of arguments and the modifiers used. The number of arguments is a simple number and the list of modifiers must include, for each modifier, its name, whether it accepts a value and, optionally, any restrictions for that value.

4.3 The Run Function

The `Run` function executes the code for the command. It is always called monadically with a two-element vector argument; the user command's name and the supplied arguments/modifiers. As a single namespace can host multiple user commands, the `Run` function uses the command name to determine the appropriate actions to perform.

4.4 The Help Function

The `Help` function reports detailed information on the user command when this is requested (by entering `]<ucmd> -?` or `]Help]<ucmd>` in a Dyalog Session). As a single namespace can host multiple user commands, the `Help` function uses the command name to determine the appropriate information to return.

When a user requests help for a particular user command, the `Help` function returns a specific set of information by default:

```
]<GROUPNAME>.<commandname>
<specific defined help information>
```

If `]UDebug` is on, then the `Help` function returns an enhanced set of information by default:

```
]<GROUPNAME>.<commandname>
```

Source: <location of the user command's script file>
Version: <version number of the user command>
Syntax: <number of arguments> only if arguments can be specified
Accepts modifiers <list of all modifiers> only if modifiers can be specified
<specific defined help information>

4.4.1 Defining Multiple Levels of Help

The specific defined help information that is presented to a user when requesting help in a Dyalog Session is dependent on the level of help requested. This level is defined to be 1 less than the number of ? characters entered after the - character; for example,]<ucmd> -?? returns the information defined for level 1 of the <ucmd> user command.

As with the predefined user commands, increasingly detailed levels of information can be provided for custom user commands. If multiple levels of help are defined, then Dyalog Ltd recommends including information to that effect in each level, for example, the information that is displayed in response to a]<ucmd> -?? request should state that more detailed information is available if]<ucmd> -??? is entered.

Any valid Dyalog algorithmic syntax can be used in the Help function to define different levels of help, for example, control structures or branching. Optionally, the different levels of help can be cumulative so that, for example,]<ucmd> -??? returns the help information for levels 0 and 1 as well as the help for level 2.

The following code fragment is an example showing how separate (non-cumulative) levels of help can be defined within the Help function:

```

▽ r←level Help Cmd
  :Select level
  :Case 0
    r←'This is basic help.'
  :Case 1
    r←'This is level 1 help.'
  :Case 2
    r←'This is level 2 help.'
  :Else
    r←'This is level 3 help.'
  :EndSelect
▽

```

In this case:

-]<ucmd> -? gives This is basic help.
-]<ucmd> -?? gives This is level 1 help.
-]<ucmd> -??? gives This is level 2 help.

-]<ucmd> -???? gives This is level 3 help.
-]<ucmd> -????? gives This is level 3 help.

The :E l s e control structure in the code fragment ensures that requests for higher levels of help than are defined return the highest-defined level rather than generating an error message.

The following code fragment is an example showing how cumulative levels of help can be defined within the H e l p function:

```
▽ r←level Help Cmd
  r←'This is basic help.'
  r,←'This is level 1 help.'
  r,←'This is level 2 help.'
  r,←'This is level 3 help.'
  r←((1+level)[≠r])r
▽
```

In these cases:

-]<ucmd> -? gives
This is basic help.
-]<ucmd> -?? gives
This is basic help.
This is level 1 help.
-]<ucmd> -??? gives
This is basic help.
This is level 1 help.
This is level 2 help.
-]<ucmd> -???? gives
This is basic help.
This is level 1 help.
This is level 2 help.
This is level 3 help.
-]<ucmd> -????? gives
This is basic help.
This is level 1 help.
This is level 2 help.
This is level 3 help.

Entering]H e l p]<ucmd> in a Dyalog Session always presents the user with the same level of help as]<ucmd> -? even if there are multiple levels of help defined.

4.5 Modifiers

Modifiers enable a user command to apply filters and rules so that an entirely new (similar) user command does not need to be written. The user command framework allows you to define the modifiers that your user command will accept. The rules when defining each modifier in the `Parse` variable are:

- If a modifier accepts characters in a set, then the `Parse` variable includes the modifier and possible values with the `€` character as a separator. For example:
`-<modifier name>€<set of characters>`
 so `-XYZ€abc012` means that the modifier `-XYZ` can accept any number and combination of characters in the set `abc012`, such as `ab2a0b`.
- If a modifier accepts specific strings, then the `Parse` variable includes the modifier and possible values with the `=` character as a separator and the strings separated by space characters. For example:
`-<modifier name>=<string1> <string2> <string3>`
 so `-XYZ=abc 012` means that the modifier `-XYZ` can accept either `abc` or `012` as a modifier value.
- If a modifier accepts any string, then the `Parse` variable includes the modifier and a `=` character with nothing after it. For example:
`-<modifier name>=`
 so `-XYZ=` means that the modifier `-XYZ` can accept any value.

For each of these three rules, enclosing the separator character within square brackets means that specification of modifier values is optional. For example, `-XYZ [=]` means that the modifier `-XYZ` can be specified without a value but will accept any value.

4.5.1 Default Modifier Values

A modifier always has an internal value. This is one of the following:

- 0 if the modifier is not included when running the user command
- 1 if the modifier is included when running the user command but no modifier value is included
- a string matching the specified modifier value

A modifier can be configured to default to a specific value in one of three ways; these approaches are shown in this section with the modifier `-X` defaulting to a modifier value of `123` (a three-element character vector).

Approach 1: Assign a default value to the modifier using the ":" character as the separator:

```
List[i].Parse←'-X:123'
```

With this approach, the default value is reported only if the modifier is not used; a value of 1 is reported if the modifier is used but no value is specified.

Approach 2: Test whether the modifier value is 0 and, if it is, then set it to the required default value.

For example:

```
:if X≡0 ♦ X←'123' ♦ :endif
```

Approach 3: Define the default value using the dyadic form of the `Switch` function (automatically defined in the namespace that is passed to the `Run` function (see [Section 4.3](#)) as its second argument).

Given the name of a modifier as a right argument:

- monadic `Switch` returns:
 - 0 if an invalid modifier name is specified
 - 0 if the modifier is not specified and no default value has been set for that modifier
 - 1 if the modifier is specified without a modifier value
 - a string matching the specified modifier value
 - a string matching the default modifier value if a modifier is not specified but a default value has been set for that modifier
- dyadic `Switch` returns:
 - the value of the left argument (default value) if an invalid modifier value is specified
 - the value of the left argument (default value) if a modifier is not specified and no default value has been set for that modifier
 - the specified modifier value if defined – however, if the value of the default is numeric then it assumes that the specified modifier value should also be numeric and transforms it into a number. This means that, if the modifier and modifier value `-X=123` is entered, the expression `99 Args.Switch 'X'` will return `(,123)` not `'123'`; the `Switch` function always returns a vector, making it very easy to differentiate between 0 (the modifier is not included when running the user command) and `,0` (a modifier value of 0 was specified when running the user command).

4.6 Arguments

Unlike modifiers, arguments do not have names. However, as arguments must be specified in a particular order and each have a specific purpose, they should be given an appropriate name in the `Help` function to make their purpose clear.

The number of arguments that a user command can take is specified in the `Parse` variable (see *Section 4.2.3* – this explains the rules for determining the value to specify there).

4.6.1 Default Argument Values

A default value can be defined for an argument – this value is automatically used if the argument is not specified when running the user command. Default values are defined within the `Run` function.

EXAMPLE

To set a default value of `'defaultfor4th'` for the 4th argument:

```
args←a.Arguments,(pa.Arguments)↓0 0 0 'defaultfor4th'
```

where `a` is the second argument supplied to the `Run` function, that is the arguments/modifiers supplied to the user command (see *Section 4.3*). In this example, the first three arguments have their default values set to 0 if they are optional arguments; if they are mandatory then any value specified here is ignored.

4.6.2 Arguments Including Space Characters

Arguments that contain space characters must be delimited with `'` or `"` characters. For example, if the user command `]NewID` must have 2 arguments supplied, *full name* and *address*, then `Parse` should be set to `'2'` and the user command is run as follows:

```
]NewID 'Morten Kromberg' 'Dyalog Ltd'
```

If the user command `]NewID` accepts 3 arguments, *firstname*, *surname* and *address*, then `Parse` should be set to `'3'` and the user command is run as follows:

```
]NewID Morten Kromberg 'Dyalog Ltd'
```

4.6.3 Minimum Number of Arguments

If a user command must have a minimum number of arguments, then `Parse` can be coded to that effect by assigning it a range of numbers of arguments, that is:

```
Parse←' <min number of args>-<max number of args>'
```

A minimum number of arguments cannot be specified without also specifying a maximum number of arguments. However, if there is no maximum number of arguments then an arbitrary high number can be used. For example, if at least three arguments must be supplied when calling a user command but there is no limit to the number of arguments that the user command can process, then `Parse` could be assigned as `Parse←'3-9999'`.

4.6.4 Maximum Number of Arguments

If a user command can only process a limited number of arguments, then `Parse` can be coded to that effect by appending `S` to the maximum number of arguments. For example, if the user command can accept 0, 1 or 2 arguments but no more, then `Parse` should be set to `'2S'`.

4.6.5 Long Arguments

The last argument can be defined to comprise anything that remains after removing the other arguments. `Parse` can be coded to that effect by appending `L` to the maximum number of arguments – any additional arguments after the maximum number is reached are merged into the last argument. For example, if the user command can accept 1 argument consisting of everything that is included when running the command, then `Parse` should be set to `'1L'`.

The long argument `L` can be appended to the maximum number of arguments `S` (see *Section 4.6.4*) to specify that any additional arguments after the maximum number has been supplied should be merged into the last one supplied. For example, if `'3SL'` is specified, then 0, 1, 2 or 3 arguments can be supplied when calling the user command but any more than this will be merged with the third argument. This means that:

```
]cmd a1 a2 a3 a4 a5 a6
```

runs the user command `cmd` with three arguments: `a1`, `a2` and `'a3 a4 a5 a6'`.

4.6.6 Summary of Argument Specification in the Parser

`Parse←'n'` where `n` can be:

- `n1` : exactly `n1` arguments must be supplied
- `n2-n3` : a minimum of `n2` arguments and a maximum of `n3` arguments can be supplied
- `n4S` : a maximum of `n4` arguments can be supplied (equivalent to `0-n4`)
- `n5L` : `n5` arguments must be supplied; if more than this are supplied then the first `n5-1` arguments are taken and the rest are merged together into the final `n5` argument

- n_6-n_7L : a minimum of n_6 arguments and a maximum of n_7 arguments can be supplied; if more than this are supplied then the first n_7-1 arguments are taken and the rest are merged together into the final n_7 argument
- n_8SL : a maximum of n_8 arguments can be supplied; if more than this are supplied then the first n_8-1 arguments are taken and the rest are merged together into the final n_8 argument (equivalent to $0-n_8L$)
- $n_9-n_{10}L$: a minimum of n_9 arguments and a maximum of n_{10} arguments can be supplied; if more than this are supplied then the first $n_{10}-1$ arguments are taken and the rest are merged together into the final n_{10} argument (equivalent to $0-n_{10}L$)

4.7 Saving Custom User Commands

Custom user commands must be saved in a **.dyalog** file (if a custom user command has been created in a namespace in a Dyalog Session, then it can be saved as a **.dyalog** file using the `]Save` user command).

The predefined user commands are located in the `[DYALOG]\SALT\spice` directory. Dyalog Ltd recommends that you save custom user commands in a different directory that is not located beneath the **SALT** directory; this is because there might be permissions issues with accessing custom commands beneath this directory and there is always the possibility that Dyalog Ltd might issue a user command with the same filename as your custom user command at a future date.

The custom user command directory must be added to the user command search path to enable the user commands within it to be detected. To do this, use the `]Settings` user command (see *Section 5.10.9*) to set the `cmddir` global parameter to the full path and name of the directory.

When adding a new directory to the list of directories searched by the user command framework, you must precede its path with a `.` character.

If the `cmddir` global parameter includes multiple directories, then the user command framework searches the directories in the order listed and retrieves the first user command it finds with the specified name. To see the list of directories (and the order in which they are searched), enter `]Settings cmddir`.

If the `]UNew` user command is used to create and save a new user command, then its location is automatically added to the list of directories searched.

4.8 Detecting New Custom User Commands

If the *newcmd* global parameter is set to *auto* and a user command is entered in a Dyalog Session that the user command framework does not recognise, then the Dyalog interpreter scans the user command directory(s) to see whether new user commands have been added. However, if the *newcmd* global parameter is set to *manual* or a change is made to the *Help* function or *List* function of an existing user command, then the user command **]UReset** must be run to force a complete reload of all user commands.

In addition, new user commands that are placed in the **MyUCMDs** directory are automatically active without needing to specify **]Settings cmdmdir -permanent**.

On the Linux operating system, the **MyUCMDs** directory is located directly under the **\$HOME** directory.

On the macOS operating system, the **MyUCMDs** directory is located directly under the **\$HOME** directory.

On the Microsoft Windows operating system, the **MyUCMDs** directory is located directly under the **%USERPROFILE%\Documents** directory.

5 Predefined User Commands

Related user commands with common features can be grouped under a single name (see *Section 3.5*). This chapter introduces the predefined groups (as summarised in *Table 5-1*) and their constituent user commands.

Table 5-1: User Command Groups

Group	Description
ARRAY	User commands that relate to arrays or variables.
CALC	User commands that manipulate data.
DEVOPS	User commands that relate to development and operations.
FILE	User commands that relate to files.
FN	User commands that relate to functions and operators.
MSWIN	User commands that relate to the Microsoft Windows operating system.
NS	User commands that relate to namespaces.
OUTPUT	User commands that change the way in which arrays are displayed in a Session.
PERFORMANCE	User commands that collect and analyse CPU consumption data.
SALT	User commands that perform the same actions as the SALT functions of the same name found in <code>□SE . SALT</code> .

Table 5-1: User Command Groups (continued)

Group	Description
SAMPLES	User commands that demonstrate the use of multiple levels of help and parsing user command lines.  This group is only displayed by]? and]?+ if the path [SALT]/study is added to the <i>cmddir</i> global parameter (see <i>Section 5.10.9</i>).
TOOLS	User commands that can assist developers by retrieving and presenting information without changing the underlying code.
TRANSFER	User commands that convert workspaces between files written using other dialects of APL or older versions of Dyalog and the current Dyalog version.
UCMD	User commands that manage the user command framework.
WS	User commands that relate to workspaces.

 For information on the precise syntax for each user command, the arguments that can be supplied to it and the modifiers that it can take, enter **]Help <cmd>** or **]? <cmd>** in a Dyalog Session.

5.1 ARRAY Group

The ARRAY group contains user commands that relate to arrays or variables.

5.1.1]Compare

This user command compares any two APL objects for which \square NC is 2 (variables) or 9 (namespaces) and returns the differences between them.

EXAMPLE

```
varA←8,1↓varB←19
]ARRAY.Compare varA varB
objects are num vectors
elements: 1 different ( $\square$ IO=1)
Var1 8 2 3 4 5 6 7 8 9 Var2 1 2 3 4 5 6 7 8 9
```

5.1.2]Edit

This user command opens the specified array in the appropriate editor:

- On the Microsoft Windows operating system:
 - the Unicode edition of Dyalog opens the Array Editor.
 - the Classic edition of Dyalog opens the `⎕WC` grid-based editor.
- On all other operating systems, the default **Edit** window is opened.

EXAMPLE

```
arr←i2 3
]ARRAY.Edit arr
```

Figure 5-1: The Array Editor (Unicode edition of Dyalog for Microsoft Windows)

5.2 CALC Group

The CALC group contains user commands that manipulate data.

5.2.1]Factors

This user command returns the prime factors of the specified integer.

EXAMPLE

```
]Factors 123456789
3 3 3607 3803
```

5.2.2]FromHex

This user command converts a list of hexadecimal representations of integers to a numeric vector.

EXAMPLE

```
]FromHex 64 100
100 256
```

5.2.3]PivotTable

This user command provides pivot table functionality; the array that is to have pivot table functionality applied to it must have no more than three columns.

EXAMPLES

```
M←(20 2ρ'C3C3C4B4C2B2D1C4A4C1B3B1C1B2A0A1D1B0C1C4'), 4 3 4 8
3 3 9 6 5 9 2 7 7 1 6 5 4 7 6 9
```

```
]PivotTable M      A default: count of unique M[;1 2]
      3 4 2 1 0 Total
C      2 3 1 3 0      9
B      1 1 2 1 1      6
D      0 0 0 2 0      2
A      0 1 0 1 1      3
Total  3 5 3 7 2     20
```

```
]PivotTable M -f=+/- A sum M[;3] by unique M[;1 2]
      3 4 2 1 0 Total
C      7 19 3 22 0     51
B      2 8 4 7 7     28
D      0 0 0 13 0     13
A      0 5 0 5 6     16
Total  9 32 7 47 13   108
```

```
]PivotTable "(5 2ρ'GrpA' 'case1' 'GrpB' 'case1' 'GrpB'
'case2' 'GrpA' 'case1' 'GrpB' 'case2'), 15" -f=+/-
      case1 case2 Total
GrpA      5      0      5
GrpB      2      8     10
Total      7      8     15
```

5.2.4]ToHex

This user command converts integers to a vector of text vectors containing the hexadecimal representation of each number. If the argument is an expression containing integers, then the expression is evaluated and the hexadecimal representation of the solution is returned.

EXAMPLE

```
]ToHex 100 256
64 100

]ToHex 100+256
164
```

5.3 DEVOPS Group

The DEVOPS group contains user commands that relate to development and operations.

5.3.1]DBuild

This user command executes one or more DyalogBuild scripts.

This user command is part of an experimental build/test framework used internally at Dyalog. Contact support@dyalog.com for more information.

5.3.2]DTest

This user command runs a selection of functions named **test_*** from a namespace, file or folder.

This user command is part of an experimental build/test framework used internally at Dyalog. Contact support@dyalog.com for more information.

5.3.3]Link

This user command links a namespace and a directory, synchronising changes.

For more information, see <https://github.com/Dyalog/link/blob/master/README.md>.

5.4 FILE Group

The FILE group contains user commands that relate to files.

5.4.1]CD

If no argument is supplied, then this user command reports the current directory; if an argument is specified, then this user command reports the current directory and then updates it to the one specified.

EXAMPLES

```
]CD
C:\Windows\system32
```

```
]CD \tmp
C:\Windows\system32
```

```
]CD
C:\tmp
```

5.4.2]Collect

This user command merges all the files that have a path/name starting with the specified pattern into a single file.

This is particularly useful when]Split has been used on a file (see *Section 5.4.8*) and the resultant files subsequently need to be reassembled.

EXAMPLE

To merge all files starting with `\tmp\file.zip` and followed by `001`, `002`, `003` and so on into a single file called `\temp\px.zip`:

```
]Collect \tmp\file.zip -newname=\temp\px.zip
```

5.4.3]Compare

This user command compares each component within a component file with the component that has the same number in a second component file.

EXAMPLE

```
]FILE.Compare fileA fileB
Comparing file <fileA>
      with <fileB>
fileA has 2 components starting at 1
fileB has 2 components starting at 1

Comparing 2 components
```

```

*** Component 2
objects are num vectors
Var1 1 2 3 4 5 Var2 1 2 3 4 5 6 7 8 9 10

*** Comparing access matrices (no difference)

```

If **fileA** comprises components 1 to 10 and **fileB** comprises components 6 to 22 then only components 6 to 10 will be compared.

5.4.4]Edit

This user command opens the specified native file as an editable text file in the standard in-Session Editor.

EXAMPLE

```

]FILE.Edit C:\Users\fiona\Samples\UTF8.txt
]FILE.Edit C:\Users\fiona\Samples\UTF16-BOM.txt

```

5.4.5]Find

This user command searches for the specified search string in, by default, **.dyalog** files in the current SALT working directory (as returned by `]Settings workdir`) and its sub-directories.

It displays a list of the files (with full paths) containing the specified string and the line numbers within each file on which the specified string occurs.

EXAMPLES

To identify all occurrences of the string "ABC" in all **.dyalog** files in the `\temp` directory and its sub-directories:

```

]FILE.Find ABC -folder=\temp

```

To identify all occurrences of the string "ABC" and all seven-letter words in all **.txt** or **.log** files in the current SALT working directory and its sub-directories:

```

]FILE.Find \b(ABC|\w{7})\b -typ=txt,log -regex

```

5.4.6]Open

This user command opens directories and files, including files that are external to Dyalog, using the appropriate program (the default program can be overridden by including the `-using=<program>` modifier). If no argument is provided, then a standard **Windows**

Explorer window is displayed in which the directory/file can be selected.

EXAMPLE

```
]Open C:\Users\jason\Desktop\document.txt
```

5.4.7]Replace

This user command searches for the specified search string in, by default, **.dyalog** files in the current SALT working directory (as returned by `]Settings workdir`) and its sub-directories and replaces it with the specified replacement string.

It displays the number of changes made.

EXAMPLES

To replace "ABC" with "XYZ" in all **.dyalog** files in the `\tmp` directory:

```
]Replace ABC XYZ -folder=\tmp
Total 23 changes made
```

To reverse every occurrence of two words that follows "Name:" in all **.dyalog** files in the current SALT working directory (for example, "Name: Ken Iverson" becomes "Name: Iverson, Ken"):

```
]Replace "Name:\s+(\w+)\s+(\w+)" "Name: \2, \1" -regex
Total 31 changes made
```

5.4.8]Split

This user command splits the specified file into the stated number of smaller files (maximum 999) of equal size or multiple individual files of the stated size.

EXAMPLES

To split **FileA** into five individual files (called **FileA-01**, **FileA-02**, and so on):

```
]Split FileA -chunk=5
```

To split **FileA** into individual files (called **FileA-01**, **FileA-02**, and so on) of 5 MB each:

```
]Split FileA -chunk=5M
```

5.4.9]ToLarge

This user command converts all small span component files in the specified directory into large span component files.

EXAMPLE

```

]ToLarge \project -recursive -verbose -backup=.32
* <C:\project\132u64b.DCF> is already 64b
*** <C:\project\to\x1.DCF> is tied
...27 files modified

```

This user command uses `FCOPY` to perform the conversion. This means that it can take a considerable amount of time to execute if there are very large files, but all the timestamps are preserved.

5.4.10]ToQuadTS

This user command takes a timestamp (for example, the last time a component within a component file was updated) and converts it into its `TS` equivalent (a vector of 7 numbers).

EXAMPLE

```

]ToQuadTS 3[]frdci 4 1
2013 9 9 23 16 28 0

```

5.4.11]Touch

This user command checks whether the specified file exists in the current/specified location and creates it if it cannot be found.

EXAMPLE

```

]Touch abc.xyz

```

5.5 FN Group

The FN group contains user commands that relate to functions and operators.

5.5.1]Align

This user command searches for comments at the end of a line of code within the specified function and aligns them to the stated column (defaults to column 40).

EXAMPLE

To align all comments at column 30 in functions that start with "HTML" and display the names of all the functions that have been modified in `)FNS` format:

```

]Align HTML* -offset=30

```

5.5.2]Calls

This user command produces the calling tree of the specified function in the specified class/namespace (defaults to the current namespace).

EXAMPLE

```

    ]Calls ClassFolder
Level 1: →ClassFolder
A Produce full path by merging root and folder name
  F:specialName
Level 2: ClassFolder→specialName
A Change any [name] into path
  F:getEnvir  F:lCase  F:uCase
Level 3: specialName→getEnvir
  F:rlb      F:splitOn  F:splitOn1st  F:SALTsetFile
Level 4: getEnvir→SALTsetFile
Level 4: getEnvir→splitOn1st
A Split on 1st occurrence of any chars in str
Level 4: getEnvir→splitOn
Level 4: getEnvir→rlb
Level 3: specialName→uCase
  F:LU
Level 4: uCase→LU
Level 3: specialName→lCase
  *:LU

```

5.5.3]Compare

This user command compares any two APL objects for which `⊖NC` is 3 (functions) or 4 (operators) and returns the differences between them (including timestamps).

EXAMPLE

```

∇fna                ∇fnb
[1] same line      [1] same line
[2] fna line 2     [2] fnb line 2
[3] same line 3    [3] same line 3
[4] A comment deleted [4] new common line

```

```

      [5] new common line      [5] A new comment
      ▾                          ▾

]FN.Compare fna fnb
-[0]  fna
+    fnb
 [1]  same line
-[2]  fna line 2
+    fnb line 2
 [3]  same line 3
-[4]  A comment deleted
 [5]  new common line
+    A new comment

```

5.5.4]Defs

This user command lists the names and definitions of all single-line dfns, dops, derived functions and trains in the active workspace.

EXAMPLE

```

]Defs
at←{ω+(ρω)†(-αα)†α}
derv←{(ιω), "box>ω*÷2}{ω+(ρω)†(-αα)†α}
pars←◦(+,×/)
rcb←{(ιω), "box>ω*÷2}

```

5.5.5]DInput

This user command is used to execute or define multi line d-expressions (dfns and dops)

EXAMPLE

```

]DInput
.....{
.....ω ω
.....}{
.....αα αα ω
.....}7
7 7 7 7

```

5.5.6]Latest

This user command lists the names of any functions changed since the specified date (default is the current system date), with the most recently changed function listed first. Dates are specified as YYYYMMDD but can be shortened to MMDD if the year of interest is the current year; a leading 0 can also then be dropped. For example, 213 is February 13th of the current year. Alternatively, the number of days, weeks or months prior to the current date can be specified using a negative number. Additional filters can also be applied, for example, only those functions that have been edited by a specific user or only the last n files that have changed.

EXAMPLES

To list all the files that have been changed since 1 January 2014:

```
    ]Latest 20140101
#.HelpExample.Help #.HelpExample.List #.HelpExample.Run
```

To list only the files that have been changed by a specific user (Pete) in the last three weeks:

```
    ]Latest ^3w -by=pete
#.HelpExample.Help
```

To list only the last two files that have been changed :

```
    ]Latest -last=2
#.HelpExample.Help #.HelpExample.List
```

5.5.7]ReorderLocals

This user command changes the order in which the local names in the header of a tradfn (optionally, recursing through the hierarchy beneath the current namespace).

EXAMPLE

To change the order in which the local names in all tradfns that start with the letter "F" are listed:

```
    □VR 'Fnml'
    ▽ Fnml;□PP;X;△;a;_;aa;Aa;aaAA;aA;□IO A locals anyone?
[1]    ...
    ▽

    ]ReorderLocals F*
3 fns processed, 1 changed
```

```

    VR 'Fnml'
  ▾ Fnml;a;aa;aA;Aa;aaAA;X;Δ;_:_IO;PP A locals anyone?
[1]   ...
    ▾

```

5.6 MSWIN Group

The MSWIN group contains user commands that relate to the Microsoft Windows operating system.

5.6.1]Assemblies

This user command only works on the Microsoft Windows operating system.

This user command lists all the .NET assemblies loaded in the current application domain.

EXAMPLE

```

    ]Assemblies
mscorlib, Version=2.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089
bridge140_unicode, Version=14.0.20631.0, Culture=neutral,
PublicKeyToken=eb5ebc232de94dcf
msvc80, Version=8.0.50727.6195, Culture=neutral,
PublicKeyToken=b03f5f7f11d50a3a
dialoqnet, Version=14.0.20631.0, Culture=neutral,
PublicKeyToken=eb5ebc232de94dcf
System.Configuration, Version=2.0.0.0, Culture=neutral,
PublicKeyToken=b03f5f7f11d50a3a
System, Version=2.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089
System.Xml, Version=2.0.0.0, Culture=neutral,
PublicKeyToken=b77a5c561934e089

```

5.6.2]Caption

This user command only works on the Microsoft Windows operating system.

This user command enables a user to change the caption of various windows in the Session.

EXAMPLES

To change the Session title to "ABC":

```
]Caption session ABC
XYZ
```

To restore the original value:

```
]Caption session''
ABC
```

To change the Editor window's title to "What's going on (XX)" where "XX" is the machine size (32/64):

```
]Caption editor "What's going on ({BITS})" -window=editor
```

This user command changes registry settings. This means that:

- All instances of this Dyalog installation are changed.
- Only users with administrator access can use this user command.

5.6.3]CopyReg

This user command only works on the Microsoft Windows operating system.

This user command copies the registry settings of the specified installed Dyalog versions to a file and, optionally, to another installed Dyalog version.

Two of the modifiers that can be specified interact to generate different outcomes; these are detailed in *Table 5-2*:

Table 5-2: Results of interactions of the *-regonly* and *-to* modifiers

		-regonly?	
		Yes	No
-to ?	Yes	.reg file: default settings (formatted for specified destination version), nothing copied into registry	.reg file: all settings, default settings copied into registry
	No	.reg file: default settings, nothing copied into registry	.reg file: all settings, nothing copied into registry

EXAMPLES

To copy all the registry settings defined for the Dyalog version 14.1 installation to the **.reg** registry settings file in the default location:

```
]CopyReg 141
```

To copy the full set of registry settings defined for the Dyalog version 14.1 installation to the **.reg** registry settings file in the **\tmp** directory:

```
]CopyReg 141 -folder=\tmp\
```

To copy only the default set of registry settings defined for the Dyalog version 15.0 installation to the **.reg** registry settings file in the default location:

```
]CopyReg 15 -regonly
```

To copy the default registry settings defined for the Dyalog 64-bit version 13.2 Unicode installation to the Dyalog 64-bit version 16.0 Unicode installation on the same machine:

```
]CopyReg "13.2 Unicode 64" -to=16U64
```

To copy only the default set of registry settings defined for the Dyalog version 14.1 installation to the **.reg** registry settings file in the default location in a format that can then be imported into a Dyalog 64-bit version 15.0 Unicode installation:

```
]CopyReg 141 -regonly -to=15U64
```

5.6.4]FileAssociations

This user command only works on the Microsoft Windows operating system and requires administrator rights.

This user command associates files that have the extension **.dws**, **.dyalog** or **.dyapp** with a specific Dyalog version. This is only relevant if you have multiple versions of Dyalog installed and want to change the version in which **.dws**, **.dyalog** or **.dyapp** files open when double-clicked on.

EXAMPLE

```
]FileAssociations
```

Figure 5-2: The *File Associations* dialog box

5.6.5]GUIProps

This user command only works on the Microsoft Windows operating system.

This user command reports the properties (and their values) of the specified GUI object or, if none is provided, the object on which the Session has focus (the object whose name appears in the bottom left corner of the Session log). This only works for GUI objects that have been created using the `□WC` syntax, not for GUI objects that have been created using other techniques.

EXAMPLE

```
't' □WC 'timer' ('active'0)
]GuiProps t
Properties of #.t Interval:1000 Event:      KeepOnClose:0
Type:Timer      Active:0      Data:
Properties of #.t
MethodList: Detach Wait
ChildList: Timer
EventList: Close Create Timer
```

5.6.6]KeyPress

This user command only works on the Microsoft Windows operating system.

This user command displays the elements of the event message vector in a dialog box when an event is triggered (that is, a key is pressed). If run from the **Session** window, data is also displayed there.

Keypress event information includes the keynumber for a particular key. This is needed when:

- setting up an Accelerator property for a GUI object.
- editing the keyboard translate **.DIN** files for the IME to enable keyboard layout customisation.
- performing some action in the keypress event callback for a particular key.

For more information on the event message vector, see the *Dyalog for Microsoft Windows Object Reference Guide*.

EXAMPLE

`]KeyPress`

Figure 5-3: KeyPress Event dialog box

5.7 NS Group

The NS group contains user commands that relate to namespaces.

5.7.1]ScriptUpdate

This user command updates scripted namespaces/classes to take account of newly added or deleted variables, functions and operators.

In Dyalog, the only way to update the source of a scripted object is to edit the source; using `⎕FX` or assignment does not update the source. This user command identifies variables, functions and operators that exist in the specified scripted object but are not part of the source and adds them to the source using `⎕FIX`. It also identifies variables, functions and operators that do not exist in the specified scripted object but are part of the source and deletes them from the source using `⎕FIX`.

EXAMPLE

```

)LOAD myns
)CS myns
V←19
⎕FX 'myfn' '2+2'

]ScriptUpdate
Added 1 variables and 1 functions

```

5.7.2]Summary

This user command returns summary information (scope, size and syntax) of each of the functions in the specified scripted namespace/class. For an explanation of the scope and syntax codes, enter `]??Summary` in a Dyalog Session.

EXAMPLE

```

]Summary ⎕SE.Parser

```

Name	Scope	Size	Syntax
Parse	P	16904	r1f
Propagate		2664	r2f
Quotes		2176	r1f
Switch		2536	r2f
deQuote		1432	r1f
fixCase		120	r2f
if		48	r2f
init	PC	13960	n1f
splitParms		3320	r1f
sqz		1064	r2f
upperCase		1152	r2f
xCut		840	r2f

5.7.3]Xref

This user command generates a cross-reference of the objects in a scripted object.

It produces a table showing all objects referred to (columns) against the function or operator that refers to them (rows). The symbols in the table describe the nature of the reference: `o` means local, `G` mean global, `F` means function, `L` means label and `!` identifies an unused localised name.

EXAMPLES

```

src←':Class cl' ':Field myfield←1'
src,←'∇foo a;var' 'a←1' 'goo' '∇'
src,←'∇goo;var' 'var←myfield' '∇'
src,←c':EndClass'
□FIX src

]Xref cl
var
myfield.
goo..
a...
↓↓↓↓
[FNS] - -
foo  oF !
goo  .Go

```

This shows that `var` appears in both `foo` and `goo`, but in `foo` it only appears in the function header. `myfield` is referenced in `goo` but is external to it, so appears as a Global to `goo`.

Dots, dashes, colons and arrows only serve as alignment decorators and have no special meaning.

```
]Xref cl -raw
```

o F !	a	foo	goo	myfield	var
Go					

5.8 OUTPUT Group

The OUTPUT group contains user commands that change the way in which arrays are displayed in a Session.

5.8.1]Box

Identical to]Boxing (see *Section 5.8.2*) – included for convenience when the auto-complete feature is not available. A function key can be defined with which to toggle]Box on and off.

5.8.2]Boxing

This user command changes the default display of arrays, functions and operators in the Session window. The output is similar to that of the]Disp user command (see *Section 5.8.3*) but without any border decoration indicating subarray shape and type.

EXAMPLE

```

i2 3
1 1 1 1 1 2 1 1 1 2 1 3
1 1 1 1 1 2 1 1 1 2 1 3
2 1 2 1 2 2 2 1 2 2 2 3

```

```

]Boxing on
Was OFF

```

```

i2 3

```

1 1	1 1 1 2	1 1 1 2 1 3
1 1	1 1 1 2	1 1 1 2 1 3
2 1	2 1 2 2	2 1 2 2 2 3

```

+ / ÷ ≠

```

+	/	÷	≠
---	---	---	---

5.8.3]Disp

This user command displays the specified array with vertical and horizontal lines separating each sub array. Characters embedded in these borders indicate sub-array shape and type.

Equivalent to the `disp` function from supplied workspace **dfns.dws**.

EXAMPLE

5.8.4]Display

This user command displays the specified array with boxes bordering each sub array. Characters embedded in the borders indicate sub-array shape and type.

Equivalent to the `display` function from supplied workspace **dfns.dws**.

EXAMPLE

5.8.5]Find

This user command detects where programs produce output while running code; each time output is produced, the generating program and the line of that program are identified on the preceding line. Lines that start with `[]←` are only shown if the `-includequadoutput` modifier is included in the call.

EXAMPLE

```

    ▽ foo
[1] 'Line not starting with []'
[2] []←'Line with []←'
    ▽

    ]OUTPUT.Find on -includequadoutput
Was off

    foo
>> Output from #.foo[1]
Line not starting with []
[]← Output from #.foo[2]
Line with []←

    ]OUTPUT.Find on
Was on

    foo
>> Output from #.foo[1]
Line not starting with []
Line with []←

```

5.8.6]Format

This user command reformats a simple text vector, a vector of text vectors (paragraphs) or literal text according to specified margins.

EXAMPLES

To display the current user's name indented by half a screen:

```

    ]Format []AN -left=.5
          karen

```

To indent the first line of the supplied text by the width of 4 characters and have a right margin the width of 88 characters:

```
]Format "'Mary had a little lamb.'" -first=4 -right=88
  Mary had a
  little lamb.
```

To indent the first line of each name by 2 characters and have a right margin the width of 78 characters:

```
A←'I wandered lonely as a cloud'
B←'That floats on high o'er vales and hills,'
C←'When all at once I saw a crowd,'
D←'A host, of golden daffodils;'

]Format A B C D -first=2 -right=78
  I wandered lonely as a cloud
  That floats on high o'er
vales and hills,
  When all at once I saw a
crowd,
  A host, of golden daffodils;
```

5.8.7]Layout

This user command reformats the specified text with margins and indentations inferred from additional spaces within the text.

EXAMPLE

```
]PW←42

T←'APL: Kenneth Eugene Iverson was a'
T,←'Canadian computer scientist noted'
T,←'for the development of the APL'
T,←'programming language in 1962.'

]Layout T
APL: Kenneth Eugene Iverson was a
Canadian computer scientist noted
for the development of the APL
programming language in 1962.
```

5.8.8]Rows

This user command impacts the display of any array that is subsequently entered into the Session by limiting the number of rows that are output.

EXAMPLE

```
]rows -fold=3
Was off
```

```
⌈10 4
```

1 1	1 2	1 3	1 4
2 1	2 2	2 3	2 4
3 1	3 2	3 3	3 4
...
10 1	10 2	10 3	10 4

5.9 PERFORMANCE Group

The PERFORMANCE group contains user commands that measure CPU consumption in various ways.

5.9.1]Profile

This user command makes it easy to locate the points in your application at which significant quantities of CPU/elapsed time is spent, facilitating the tuning process.

For more information, see the *Dyalog Application Tuning Guide*.

EXAMPLE

```
)LOAD dfns
]Profile -expr="ρqueens 8"
12
```

Figure 5-4: The JProfile Dashboard

5.9.2]RunTime

This user command measures and reports the average CPU time and elapsed time required to execute each of the specified APL expressions (if the expression includes spaces then it must be enclosed in quotation marks).

EXAMPLE

To benchmark a single expression by executing that expression once:

```

]RunTime {+/1=wv1w}"i1000
* Benchmarking "{+/1=wv1w}"i1000"
      (ms)
CPU (avg):   15
Elapsed:     20

```

To benchmark a single expression by executing that expression repeatedly for 1 second and then averaging the results:

```

]RunTime {+/1=wv1w}"i1000 -repeat=1s
* Benchmarking "{+/1=wv1w}"i1000", repeat=1s
      Exp

```

5.10.1]Clean

Analogous to `SE.SALT.Clean`.

This user command removes all the tags associated with SALT from each object in the workspace. Running this user command means that SALT no longer saves changes that are made in the workspace to the objects that were untagged.

EXAMPLES

To remove the SALT tags from all APL objects in the active workspace:

```
]Clean
```

To remove the SALT tags from APL objects objA and objB in the active workspace and then delete the files associated with those two objects:

```
]Clean objA objB -deletefiles
```

5.10.2]Compare

Analogous to `SE.SALT.Compare`.

This user command identifies the differences between two files.

EXAMPLE

```
]SALT.Compare C:\Users\andy\Desktop\abc.dyalog
C:\Users\andy\Desktop\abc2.dyalog
```

```
Comparing C:\Users\andy\Desktop\abc.dyalog
with C:\Users\andy\Desktop\abc2.dyalog
```

```
[0]      cmpx←{           A Approx expression timings.
-[1]      α←θ           A options: raw cpu cols.
+        α←θ           A options: raw cp.
[2]      1≡≡,ω:α ∇c,ω  A single expression: enclose.
[3]      α{             A options.
-[4]      (±ω)-□AI      A time of α expr-iterations.
[5]      }{□IO □ML←0 1  A local sysvars (see Notes).
[6]      dflt←{ω+α×ω=0} A α default if ω=0.
```

5.10.3]List

Analogous to `SE.SALT.List`.

This user command lists the files/directories in a specified location (by default, this is the [SALT] directory.

EXAMPLE

```

]List
Type   Name     Versions  Size  Last Update
<DIR>  core                2015/03/10 10:41:19
<DIR>  lib                2015/03/10 10:41:19
<DIR>  spice              2015/03/20 10:44:56
<DIR>  study              2015/03/10 10:41:19
<DIR>  tools              2015/03/10 10:41:19

```

5.10.4]Load

Analogous to □SE . SALT . Load.

This user command loads the latest (highest numbered) version of an APL object into the namespace that the user command is run in. By default, the link between the loaded APL object and its source is maintained and the loaded APL object is assigned a global name.

The result is affected by the presence of the `-noname` modifier:

- if `-noname` is specified, then the result is the value of the APL object loaded
- if `-noname` is not specified, then the result depends on the nameclass of the APL object loaded:
 - if the APL object loaded has a nameclass of 9, then a reference to the loaded namespace is returned.
 - if the APL object loaded has a nameclass of 2, 3 or 4, then the name of the function/variable/operator loaded is returned.

EXAMPLE

```

]Load C:\Users\jason\Desktop\DIR\abc
#.abc

```

5.10.5]Refresh

This user command reloads the most recent version of all SALTed objects that have been changed. This situation can occur if you)LOAD a workspace that contains stale objects (for example).

EXAMPLE

```

]Refresh
8 objects refreshed

```

5.10.6]RemoveVersions

Analogous to `SE.SALT.RemoveVersions`.

This user command deletes a version (or range of versions) of a versioned file and returns the number of versions that have been deleted.

EXAMPLE

```

]List \myproject -versions
Type Name      Version  Size  Last Update
myprog [18]      150   2015/03/30 13:61:02
myprog [17]      215   2015/03/29 16:16:31
myprog [16]      163   2015/03/28  9:88:92
myprog [15]      105   2015/03/26 10:80:47
myprog [14]      120   2015/03/21 11:22:53
myprog [13]      135   2015/03/12 20:09:69
myprog [12]      104   2015/03/02 11:83:86

]RemoveVersions \myproject\myprog -all -noprompt
7 versions deleted.

]List \myproject
Type Name      Versions  Size  Last Update
myprog                10   2015/03/30 18:53:17

```

5.10.7]Save

Analogous to `SE.SALT.Save`.

This user command saves an APL object in a native text file and returns the full path and name of the file that it saves. APL objects that are already SALTed are saved in the original location by default.

EXAMPLE

To save APL object ABC as a file called **abc.dyalog** in directory **DIR** (creating directory **DIR** if it does not already exist):

```

]Save ABC C:\Users\jason\Desktop\DIR\abc -makedir
C:\Users\jason\Desktop\DIR\abc.dyalog

```

5.10.8]Set

Analogous to `SE.SALT.Settings`.

Identical to `]Settings` (see *Section 5.10.9*) – included for convenience when the auto-complete feature is not available.

5.10.9 `]Settings`

Analogous to `SE.SALT.Settings`.

The values of certain global parameters are retrieved at the start of a Dyalog Session. These Session parameters remain active for the Session unless they are modified – one way in which they can be modified is with the `]Settings` user command.

EXAMPLES

To return the current values of the Session parameters:

```
]Settings
compare      apl
cmddir       C:\Program Files\Dyalog APL 16.0 Unicode\SALT\Spice
debug        0
editor       notepad
edprompt     1
mapprimitives 1
newcmd       auto
track
varfmt       xml
workdir      C:\Program Files\Dyalog APL 16.0 Unicode\SALT
```

To remove the requirement to answer prompts when saving objects and have this change persist between Sessions:

```
]Settings edprompt 0 -permanent
```

The global parameters that can be changed by running the `]Settings` user command can also impact SALT functionality – for more information on SALT see the *SALT User Guide*.

The global parameters that impact user commands are:

- `cmddir` – the full path to the directory (or list of directories) from which to retrieve user commands
- `debug` – specifies the level of debugging to use. Possible values are:
 - 0 : no debugging and report errors in the environment
 - >0 : stop if an error is encountered
- `edprompt` – specifies whether a user is prompted for confirmation to overwrite the file when modifying a script. Possible values are:

- 0 or n : the user is never prompted for confirmation
- 1 or y: the user is prompted for confirmation each time a script is modified
- *newcmd* – specifies when new user commands become effective in the user interface. Possible values are:
 - auto : new commands are detected automatically
 - manual : new commands do not become effective until the user command `]UReset` is run.

The default value for *newcmd* is *auto* except on the Raspberry Pi, where the default value is *manual*.

5.10.10]Snap

Analogous to `SE.SALT.Snap`.

Although the `]Save` user command enables individual APL objects to be saved, saving all the APL objects in a workspace using the `]Save` user command would be a repetitive process. Instead, the `]Snap` user command performs a bulk save of every APL object in the workspace in individual native text files – all new APL objects are saved to the specified directory and all modified APL objects are saved to the appropriate location. A list of the names of the APL objects that have been successfully saved is returned. If the `]Snap` user command stops for any reason, then everything that has already been saved remains saved and a list of the names of the APL objects that have been successfully saved is returned.

EXAMPLE

```
a←1
'myns'⌈ns'a'

]Snap
#.a #.myns.a
```

5.11 TOOLS Group

The TOOLS group contains user commands that can assist developers by retrieving and presenting information without changing the underlying code.

5.11.1]ADoc

This user command generates HTML documentation from script(s) and displays it in an internet browser window.

To view the complete ADoc documentation in a browser window:

```
]???ADoc
```

5.11.2]Calendar

This user command displays a calendar for the specified month and year (omitting both arguments returns the current month in the current year, omitting the year returns the specified month in the current year, omitting the month returns every month in the specified year).

EXAMPLE

```
]Calendar 6 1974
June 1974
Su Mo Tu We Th Fr Sa
 1
 2 3 4 5 6 7 8
 9 10 11 12 13 14 15
16 17 18 19 20 21 22
23 24 25 26 27 28 29
30
```

5.11.3]Chart

This user command opens the Chart Wizard and SharpPlot Chart Viewer to display the specified expression.

EXAMPLE

```
]Chart {+/1=ωvιω}''ι1000
```

Figure 5-5: The Chart Wizard and SharpPlot Chart Viewer

5.11.4]Demo

This user command provides a playback mechanism for live demonstrations of code written in Dyalog. It takes a script (the specified text file) name as an argument and executes each APL line in it after displaying it on the screen. A function key pair can be defined with which to step forwards and backwards through the script being demonstrated.

EXAMPLE

```
]Demo \tmp\mydemo
```

5.11.5]Help

This user command opens Dyalog's online documentation on (or provides a URL for) any APL concept.

EXAMPLES

```
]Help           A opens browser on help front page
]Help [F5] -url  A gives link to Domino page
]Help ]Save      A displays help for the ]Save user command
```

5.11.6]Version

This user command reports the version numbers of Dyalog, the operating system, SALT, UCMD and .NET for the current Session, as well as the build ID and workspace version. If the name of a file containing a workspace is specified as an argument, then the minimum version of Dyalog necessary to)LOAD that workspace is returned.

EXAMPLE

```
]Version
Dyalog 16.0.29236 64-bit Unicode, BuildID f37c69de
OS      Windows-64, Windows 7 or Windows Server 2008 R2
SALT    2.7
UCMD    2.2
.NET    4.0
WS      16.0

]Version C:\Users\fiona\Samples\wsA.dws
14.0
```

5.12 TRANSFER Group

The TRANSFER group contains user commands that convert workspaces between files written using other dialects of APL or other versions of Dyalog and the current Dyalog version. For more information, see the *Dyalog Workspace Transfer Guide*.

5.12.1]In

This user command imports workspaces between files written using other dialects of APL or older versions of Dyalog and the current Dyalog version.

5.12.2]Out

This user command exports workspaces written using the current Dyalog version into files that are valid for other dialects of APL or older versions of Dyalog.

5.13 UCMD Group

The UCMD group contains user commands that manage the user command framework.

5.13.1]UDebug

The `-flags` modifier should only be used with this user command as directed by Dyalog Ltd.

This user command facilitates the debugging of custom user commands. When a space followed by a `-` character is added as the last item of the user command and the user command is executed, the `-` character is removed, a stop is set on line 1 of the Run function to suspend its execution and the **Trace** window is opened when execution reaches that line.

If the namespace containing the user command is within the current namespace, then that version of the namespace is used rather than the script on file.

5.13.2]ULoad

This user command loads the namespace associated with the specified user command into the active workspace. If a user command is specified that exists in different groups (for example, `]ULoad Compare`), all the possibilities are loaded.

5.13.4]UNew

This user command opens a template that can be used to input the basic information pertaining to a new user command.

A **New User Command Wizard** is available on the Microsoft Windows operating system (press **F1** for details when running it).

EXAMPLE

]UNew

Figure 5-6: The New User Command Wizard, with and without the Use modifiers (switches) checkbox selected (Microsoft Windows only)

5.13.5]UReset

This user command forces a rebuild of the user command cache file. This is necessary to pick up changes made to files containing user commands (unless the Session is restarted, in which situation the cache is automatically rebuilt, or the global *newcmd* parameter has been set to auto – see *Section 5.10.9*).

EXAMPLE

]UReset

89 commands reloaded

5.13.6]USetup

This user command is used to initialise the **setup.dyalog** file in which Session preferences are customised and modified, for example, configuration of program function (PF) keys. It is analogous to `□LX` in the Dyalog interpreter and is always called when the interpreter is started.

The directories in which `]USe t up` searches for a **setup.dyalog** file depends on the operating system.

On the Linux operating system, `]USe t up` searches for a **setup.dyalog** file in the **/home/<user>/myUCMDs** directory and the **/home/<user>/dyalog/myUCMDs** directory.

On the macOS operating system, `]USe t up` searches for a **setup.dyalog** file in the **/Users/<user>/myUCMDs** directory and the **/Users/<user>/dyalog/myUCMDs** directory.

On the Microsoft Windows operating system, `]USe t up` searches for a **setup.dyalog** file in the **%USERPROFILE%\Documents\myUCMDs** directory.

If no **setup.dyalog** file is found in any of these locations, then `]USe t up` searches in all *SALT workdir* directories.

EXAMPLE

```
]USetup -info
C:\Users\john\Documents\MyUCMDs\setup.dyalog 0
```

5.13.7]UVersion

This user command reports the framework version number, full name, source file location, version number, revision number and last commit information for a specified user command.

EXAMPLE

```
]UVersion Boxing
framework: 2.3
command: ]OUTPUT.Boxing
source: C:\Program Files\Dyalog\Dyalog APL-64 17.0
Unicode\SALT\Spice\output.dyalog
version: 1.30
revision: 33005
commit: 2018 05 01 Adam: help tweaks
```

5.14 WS Group

The WS group contains user commands that relate to workspaces.

5.14.1]Check

This user command performs a workspace integrity check, comparing the contents of the active workspace against any scripted namespaces and identifying items that occur in one and not the other.

EXAMPLES

```
]Check
No problem found.
```

```
⊠FIX ':namespace X' 'a←19' ':endnamespace'
X.⊠FX 'Foo' '123'
X.abc←90
]check
```

These extra objects are found in scripted #.X: Foo abc

5.14.2]Compare

This user command compares any two workspaces and returns the size difference and the APL object differences between them; it can be thought of as a combination of the]ARRAY.Compare and]FN.Compare user commands running at a workspace level.

EXAMPLE

```
]WS.Compare C:\Users\fiona\Samples\wsA.dws
C:\Users\fiona\Samples\wsB.dws
* comparing C:\Users\fiona\Samples\wsA.dws
  with C:\Users\fiona\Samples\wsB.dws
```

NOTE: total sizes differ by 248 bytes.

<...etc...>

5.14.3]Document

This user command lists and details the contents (namespaces, functions, operators and variables) of your workspace.

EXAMPLES

To display the contents of the workspace on the screen (this workspace only contains a single variable, name←3):

```

    ]Document
    )WSID
CLEAR WS
    )FNS
    )VARS
name
    name (type=I ρρ=0 ρ=θ)
3
    )OBS

```

To output the contents of the workspace to a file:

```

    ]Document -file=C:\Users\karen\Samples\tmp.txt
Output file = C:\Users\karen\Samples\tmp.txt

```

5.14.4]FindRefs

This user command attempts to find all references in a workspace and identify where they are referenced from.

EXAMPLES

```

    )CLEAR
clear ws
    A←[]NS '' ♦ B←C←D←A
    V←0 C 2 99

    ]FindRefs
#: followed 6 pointers to reach a total of 2 "refs"
Name
#
#.B+4 more

    ]FindRefs -alias
#: followed 6 pointers to reach a total of 2 "refs"

```

```

Name  Alias 1  Alias 2  Alias 3  Alias 4
#
#.B   #.C     #.D     #.V[2]  #.A (DF=#.[Namespace])

      ]FindRefs -alias=3
#: followed 6 pointers to reach a total of 2 "refs"

Name  Alias 1  Alias 2  Alias 3
#
#.B   #.C     #.D     #.V[2]+1 more

      'X' []NS ''
      A.t←X
      X.z←A

      ]FindRefs -loop
#: followed 31 pointers to reach a total of 3 "refs"

Name
#
#.B+11 more
#.X+11 more

1 loop found:

Loop #1: #.B   → #.X
      #.X = #.B.t
      #.B = #.X.z

      )CLEAR
clear ws
[]FIX ':class B' ':endclass'
[]FIX ':class A:B' ':endclass'
[]EX 'B'

      ]FindRefs A
#.A: followed 1 pointers to reach a total of 1 "refs"

Name
#.A

#.A's base class is missing: #.B

```

5.14.5]FnsLike

This user command returns a list of APL objects for which `⊔NC` is 3 (functions) or 4 (operators) that exist in the current namespace (and, optionally, in the hierarchy beneath it) and match the specified pattern.

EXAMPLES

To find all APL objects for which `⊔NC` is 3 or 4:

```
      ]FnsLike
big      det      else      getfile  life
```

To find all APL objects for which `⊔NC` is 3 or 4 that contain the letter "e" in their name:

```
      ]FnsLike *e*
det      else      getfile  life
```

5.14.6]Locate

This user command searches for the specified string in the current namespace.

EXAMPLES

To search for the string "queens":

```
      ]Locate queens
      ▽ #.queens (3 found)
[0]  queens←{⊔IO ⊔ML←0 1      A The N-queens problem.
      ^                      ^
[24] chars←'·⊗'[(↑ω)∘.=ια] A char array of placed queens.
                        ^
```

To search for the string "queens" irrespective of case and ignoring comments:

```
      ]Locate queens -insensitive -exclude=C
      ▽ #.queens (1 found)
[0]  queens←{⊔IO ⊔ML←0 1      A The N-queens problem.
      ^
```

5.14.7]Map

This user command displays the structure of the specified namespace (or the current namespace if none is specified) in terms of its constituent variables, functions and operators (identified with `~`, `▽` and `∘` respectively). Sub-namespaces are displayed

recursively.

This user command uses the `tree` function from supplied workspace `dfns.dws`.

EXAMPLE

```

    ]Map [SE.Dyalog
[SE.Dyalog
·   Callbacks
·   ·   ▽ WSLoaded
·   SEEd → [SE.[SessionEditor]
·   Utils
·   ·   ~ Version lc uc
·   ·   ▽ cut disp display dmb drvSrc dtb fromXML fromto lcase
psumum repObj showCol showRow toMatrix toVector toXML trimEnds
txtreplace ucase where
·   ·   SALT_Data → [SE.[Namespace]

```

5.14.8]NamesLike

This user command returns a list of all APL objects (irrespective of [NC]) that exist in the current namespace (and, optionally, in the hierarchy beneath it) and match the specified pattern.

EXAMPLES

To find all APL objects that contain the letter "a" in their name:

```

    ]NamesLike *a*
aplUtils.9          disableSALT.3      enableSALT.3
commandLineArgs.2  disableSPICE.3      enableSPICE.3

```

To find all APL objects that contain the letter "a" in their name without showing their nameclass:

```

    ]NamesLike *a* -noclass
aplUtils          disableSALT      enableSALT          commandLineArgs
disableSPICE      enableSPICE

```

5.14.9]Nms

This user command returns a list of all APL objects (irrespective of [NC]) that exist in the current namespace (and, optionally, in the hierarchy beneath it) and match the specified pattern.

Almost identical to `]NamesLike` (see *Section 5.14.8*) but does not have a modifier for removing the nameclass when displaying results. This slight restriction means that it matches IBM's APL2 system command `)NMS`.

EXAMPLE

```
]Nms *a*
aplUtils.9      disableSALT.3      enableSALT.3
commandLineArgs.2  disableSPICE.3      enableSPICE.3
```

5.14.10 `]ObsLike`

This user command produces a list of APL objects for which `⊞NC` is 9 (namespaces) that exist in the current namespace (and, optionally, in the hierarchy beneath it) and match the specified pattern.

EXAMPLES

To find all APL objects for which `⊞NC` is 9:

```
]ObsLike
NStoScript      aplUtilities      test
```

To find all APL objects for which `⊞NC` is 9 that contain the letter "e" in their name:

```
]ObsLike *e*
aplUtilities      test
```

5.14.11 `]Peek`

This user command executes the specified expression in a temporary copy of the workspace; any changes made are discarded on termination of the user command, meaning that the current workspace is unchanged.

This user command copies the specified workspace into a temporary namespace in the current process and executes the specified expression in that namespace. It is used to view, rather than to change, a saved workspace; any changes made in the copy are discarded on termination of the command.

EXAMPLE

Execute the **queens** program from supplied workspace **dfns.dws**:

```
]Peek dfns 0 disp queens 5
```

5.14.12]SizeOf

This user command produces a list of all APL objects that exist in the current namespace and match the specified pattern along with their size (in bytes) in decreasing order.

EXAMPLE

```

)obs
NStoScript      aplUtils      test

)vars
CR      DELINS  Describe      FS

]SizeOf -top=2 -class=2 9
NStoScript 132352      aplUtils      40964

```

5.14.13]VarsLike

This user command returns a list of APL objects for which `⊞NC` is 2 (variables) that exist in the current namespace (and, optionally, in the hierarchy beneath it) and match the specified pattern.

EXAMPLES

To find all APL objects for which `⊞NC` is 2:

```

]VarsLike
CR      DELINS  FS

```

To find all APL objects for which `⊞NC` is 2 that contain the letter "s" in their name:

```

]VarsLike *S*
DELINS  FS

```

A SAMPLES Group

The SAMPLES group contains user commands that demonstrate the use of multiple levels of help and parsing user command lines.

The user commands in this group are not like those in other groups; they do not provide any useful functionality but their code can be examined to assist with understanding when creating custom user commands. This can be achieved by opening them in any text editor, for example, Microsoft Notepad.

This group is only available if `]Settings cmdmdir ,[SALT]/study` is issued.

A.1]UCMDHelp

An example of a custom user command that defines multiple levels of help information in the Help function, selectable by the number of question marks supplied by the user, for example, `]<ucmd> -???`.

To open the code for this user command in the Editor:

```
]ULoad UCMDHelp
Namespace #.HelpExample now contains source for ]SAMPLES.UCMDHelp
from <full path>\SALT\study\SampleHelp.dyalog
)ED HelpExample
```

A.2]UCMDNoParsing

An example of a custom user command that does not use parsing; the argument is the entire string after the command name.

To open the code for this user command in the Editor:

```
]ULoad UCMDNoParsing
Namespace #.anyname now contains source for ]SAMPLES.UCMDNoParsing
from <full path>\SALT\study\Sample.dyalog
)ED anyname
```

A.3]UCMDParsing

An example of a custom user command that uses parsing; the string after the command name is parsed and turned into a namespace containing the arguments (tokenised) and each of the identified modifiers.

To open the code for this user command in the Editor:

```
]ULoad UCMDParsing
Namespace #.anyname now contains source for ]SAMPLES.UCMDParsing
from <full path>\SALT\study\Sample.dyalog
)ED anyname
```

B Example User Commands

This appendix includes examples illustrating the construction of user commands.

The examples in this appendix have been created to illustrate different aspects of user commands. This means that they do not necessarily follow an efficient workflow process or best coding practice.

B.1 Example: Basic User Command Definition

This example illustrates the definition of a basic user command.

A new user command called `Time` is required to display the local time. The necessary functions are defined in a namespace called `timefns`:

```
:Namespace timefns

  ML IO←1      A set to avoid inheriting external values

  ▽ r←List
    r←NS"1p←"  A r is a vector of length 1 with the
                A item set to be a ref to a namespace
    r.(Group Parse Name)←'TimeGrp' '' 'Time'
    r[1].Desc←'Time example Script'
  ▽

  ▽ r←Run(Cmd Args)
    r←1↓,'c:=,ZI2'FMT TS[4 5 6]  A show time
  ▽

  ▽ r←Help Cmd
    r←'Time (no arguments)'
  ▽

:EndNamespace
```

In this example:

- The `List` function sets the four variables `Desc`, `Name`, `Group` and `Parse` to `'Time example Script'`, `'Time'`, `'TimeGrp'` and `''` respectively.
- The `Run` function only needs to call `TS` so the command name and any supplied arguments are ignored. This function also formats the time into a user-friendly format.
- The `Help` function identifies that there is only one user command in the namespace (there is only one user command name, `Time`, defined) and returns the appropriate information for that user command.

Running this user command in a Dyalog Session returns three numbers; these three numbers are the current time, indicating the hour (according to the 24 hour clock), the number of minutes past the hour and the number of seconds elapsed respectively.

```
]Time -?
```

```
]TIMEGRP.Time
```

```
Time (no arguments)
```

(the same result is returned if `]Time -??` or `]Help]Time` is entered)

```
]Time
13:05:09
```

(indicating that the current system time is 13:05 and 9 seconds)

B.2 Example: Cross-Operating System Definition

This example illustrates the inclusion of two different user commands within a single namespace, different techniques for achieving the same result depending on the operating system being used and using breakout without user commands.

Although the current system time returned by the `Time` user command (see *Section B.1*) is useful, it might be more relevant to have a choice of displaying local time or UTC (Co-ordinated Universal Time). To do this, a new user command called `UTC` is required. As this is closely related to the `Time` user command, it should be created in the same namespace; this involves adding a new function called `Zulu` and modifying the `Run`, `List` and `Help` functions.

To illustrate the ability of a user command to obtain information through a breakout call to .NET, this example also includes options in the Run function that are dependent on the operating system that the Dyalog Session is being run on (.NET is only valid when running on the Microsoft Windows operating system). These options ensure that the same user command is cross-system compatible for Microsoft Windows and UNIX.

```
:Namespace timefns
```

```

ML IO+1      A set to avoid inheriting external values
▽ r←List
  r←NS`2pc`  A r is a vector of length 2 with the
              A items set to be refs to namespaces
  r.(Group Parse)←c'TimeGrp' ''
  r.Name←'Time' 'UTC'
  r.Desc←'Show local time' 'Show UTC time'
▽
▽ r←Run(Cmd Args);dt
  :If 'Windows' ≡ 7↑>'.'WG 'APLVERSION'  A If Windows
    USING←'System'
    dt←DateTime.Now
    :If 'UTC'≡Cmd
      dt←Zulu dt
    :EndIf
    r←(r⌵'')↓r←dt
  :Else
    dt←('UTC'≡Cmd)/'TZ=UTC'  A If not Windows
    r←SH dt,' date +"%H:%M:%S"'  A set timezone
                                A and get the time
  :EndIf
▽
▽ r←Help Cmd;which
  which←'Time' 'UTC'⌵Cmd
  r←which>'Time (no arguments)' 'UTC (no arguments)'
▽
▽ r←Zulu date
  A Use .NET to retrieve UTC info
  r←TimeZone.CurrentTimeZone.ToUniversalTime date
▽
:EndNamespace
```

In this example:

- The `List` function is amended to allow for two function definitions in the four variable definitions:
 - `Desc` is set to to `'Show local time' 'Show UTC time'` (two values, therefore the first applies to the first user command and the second applies to the second user command)
 - `Name` is set to `'Time' 'UTC'` (two values, therefore the first applies to the first user command and the second applies to the second user command)
 - `Group` is set to `←TimeGrp` (only one value so applied to both user commands)
 - `Parse` is set to `' '` (only one value so applied to both user commands)
- The `Run` function is amended to use the `Cmd` argument to determine which user command is being run (any further supplied arguments are still ignored). The operating system on which the Dyalog Session is being run is then identified; different actions are taken depending on whether the operating system is Microsoft Windows or UNIX (if neither, then a message is returned). The operating system is then used to determine the current system time rather than the APL system function `⌈TS`, for example, if the UTC user command is being run on a Microsoft Windows operating system, then the `Run` function calls the `Zulu` function. The `Run` function also formats the resulting time into a more user-friendly format irrespective of the operating system and user command.
- The `Help` function is amended to enable it to identify that there are two user commands in the namespace (there are two user command names, `Time` and `UTC`, defined) and return the appropriate information according to which name is specified.
- The `Zulu` function is added to retrieve the UTC time through a .NET call – this function is only called if the `Run` function identifies that the Dyalog Session is running on a Microsoft Windows operating system and the `UTC` user command is specified.

After changing the code but before running these user commands, the `URset` user command should be run to force a cache file update (otherwise the code changes will not be detected).

The `Time` and `UTC` user commands can now be run from a Dyalog Session:

```
]TimeGrp -?
```

```
TIMEGRP:
```

```
Time Show local time in a city
```

```
UTC Show UTC time
```

```
]Time -?
```

```
]TIMEGRP.Time
```

Time (no arguments)

(the same result is returned if `]Time -??` or `]Help]Time` is entered)

```
]Time
13:17:34
```

(indicating that the current system time is 13:17 and 34 seconds)

```
]UTC -?
```

]TIMEGRP.UTC**UTC (no arguments)**

(the same result is returned if `]UTC -??` or `]Help]UTC` is entered)

```
]UTC
12:18:15
```

(indicating that the co-ordinated universal time is 12:18 and 15 seconds)

B.3 Example: Optional Arguments

This example illustrates the creation of a user command with an optional argument.

Although the `Time` and `UTC` user commands return the local time and UTC respectively (see *Section B.2*), they only work for the location in which the system is located. To return the time in different locations, new functions could be defined for each location and the `Run`, `List` and `Help` functions modified accordingly. Alternatively, the `Run` function can be modified to use the location as an argument to compute the time (this does not take account of daylight saving time). Using this second approach the `timefns.dyalog` file can be modified as follows (example assumes the Microsoft Windows operating system only):

```
:Namespace timefns
```

```
  [ML [IO←1      A set to avoid inheriting external values
```

```
  ▽ r←List
```

```
    r←[NS''2ρ←'      A r is a vector of length 2 with the
                    A items set to be refs to namespaces
```

```
    r.(Group Parse)←c'TimeGrp' ''
```

```
    r.Name←'Time' 'UTC'
```

```
    r.Desc←'Show local time in a city' 'Show UTC time'
```

```
  ▽
```

```
  ▽ r←Run(Cmd Args);dt;offset;cities;diff;city;lcity;ix
```

```

[]USING←'System'
dt←DateTime.Now
:Select Cmd
:Case 'UTC'
  dt←Zulu dt
:Case 'Time'
  :If 0≠pcity←Args~' '
    offset←CityTimeOffset city
    'Unknown city'[]SIGNAL 11p~0≡offset
    diff←[]NEW TimeSpan(3↑offset)
    dt←(Zulu dt)+diff
  :EndIf
:EndSelect
r←(r↑' ')↓r←dt
▽
▽ r←Help Cmd;which
  which←'Time' 'UTC'↓cCmd
  r←which>'Time [city]' 'UTC (no arguments)'
▽
▽ r←Zulu date
  A Use .NET to retrieve UTC info
  r←TimeZone.CurrentTimeZone.ToUniversalTime date
▽
▽ r←CityTimeOffset city;lcity;cities;ix;offsets
  cities←'l.a.' 'montreal' 'copenhagen' 'sydney'
  offsets←-8 -5 1 10
  r←θ
  lcity←(819I)city
  ix←cities↓clcity
  :If ix≤pcities
    r←ix[]offsets
  :EndIf
  A Assume no match
  A Name to lowercase
  A Find city in cities
  A If present,
  A return the offset
  A [else return θ]
▽
:EndNamespace

```

In this example:

- The `List` function has one small amendment to the description of the `Desc` variable for the first user command.
- The `Run` function still uses the `Cmd` argument to determine which user command is being run; different actions are taken according to which is specified. If the `Cmd` argument is `UTC` then the function proceeds as before. However, if the `Cmd` argument is `Time` then the function now takes the second argument into account

and passes it to the `CityTimeOffset` function (the `Args~' '` expression removes any extraneous spaces in the name of the city, so that a user can enter (for example) `'l.a.'` or `'l. a.'` and get a valid result) If the `CityTimeOffset` function returns an offset value then the `Run` function uses this to calculate the time in the specified city, otherwise it generates an "Unknown city" error message.

- The `Help` function has one small amendment to state that an optional argument specifying the location can be included when running the `Time` user command.
- The `Zulu` function remains unchanged.
- The `CityTimeOffset` function is added to determine whether the second argument matches the name of one of the cities that have had time offsets defined and return the appropriate offset if a match is found. The name of the city entered when running the user command is made case insensitive by converting them to lower case with the `(819I)` expression.

After changing the code but before running these user commands, the `JUReset` user command should be run to force a cache file update (otherwise the code changes will not be detected).

The `Time` and `UTC` user commands can now be run from a Dyalog Session:

```
]Time -?
```

```
]TIMEGRP.Time
```

```
Time [city]
```

(the same result is returned if `]Time -??` or `]Help]Time` is entered)

```
]Time
13:17:34
```

(indicating that the current system time is 13:17 and 34 seconds)

```
]Time l.a.
04:17:51
```

(indicating that the current time in Los Angeles, ignoring daylight saving time, is 04:17 and 51 seconds)

```
]Time l.x.
* Command Execution Failed: Unknown city
```

(an invalid city was specified)

```
]UTC -?
```

```
]TIMEGRP.UTC
```

UTC (no arguments)

(the same result is returned if]UTC -?? or]Help]UTC is entered)

```
]UTC
06:08:30
```

(indicating that the local co-ordinated universal time is 6:08 and 30 seconds)

```
]TimeGrp -?
TIMEGRP:
  Time  Show local time in a city
  UTC   Show UTC time
```

B.4 Example: The Parse Variable

This example illustrates use of the Parse variable; by setting this to non-empty values, the user command framework is able to handle arguments and modifiers.

For more information on the Parse variable, see *Section 4.2.3*. For more information on modifiers and modifier values, see *Section 4.5*. For more information on arguments, see *Section 4.6*.

A new user command called Number is required to display either the age of the specified person or to convert a decimal number into its Hexadecimal equivalent. The necessary functions are defined in a namespace called number:

```
:Namespace number
  ML IO+1      A set to avoid inheriting external values
  ▽ r←List
    r←NS"1p<"
    r.(Group Parse Name Desc)←'AgeHex' '' 'Number' 'Gives age
or Hexadecimal format'
  ▽
  ▽ r←Run(Cmd Args);N;H;alph;Name;Names
    r←⊖
    Names←Args.Arguments
    :For Name :In Names
      :Select Name
      :Case 'Fiona'
        r,←40
      :Case 'Andy'
```

```

        r,←51
    :Else
        :If ^/Name€[]D    # If all digits...
            N←[16*(#Name)
            H←(Nρ16)τ(#Name)
            alph←'0123456789ABCDEF'
            r,←calph[[]IO+H]
        :Else
            r,←c'Unrecognised Name'
        :EndIf
    :EndSelect
:EndFor
▽
▽ r←Help Cmd
    r←'Enter either a person's name to return their age or a
    number to return the Hexadecimal equivalent'
▽
:EndNamespace

```

In this example, the `Parse` variable is empty – this means that the `Run` function takes everything following the command name as a simple character vector. However, if a valid name is entered with the expectation of having that person's age returned, then an error message is generated:

```

]Number Fiona
* Command Execution Failed: SYNTAX ERROR

```

The same error message is generated if a decimal number is entered with the expectation of its Hexadecimal equivalent being returned:

```

]Number 42
* Command Execution Failed: SYNTAX ERROR

```

This error arises because the user command is expecting a namespace as its input and instead it is receiving a simple character vector.

These errors arise because the `Args` parameter in the `Run` function is a simple character vector rather than a namespace; this is due to the empty `Parse` variable. Populating the `Parse` variable means that the `Args` parameter becomes a namespace.

For this example, the only changes that will be made to the user command's code are to its `Parse` variable definition.

To enable the user command to perform the necessary namespace conversion, the `Parse` variable is changed from `' '` to `'2S'` – this means that the user command can accept 0, 1 or 2 arguments but no more (for more information on this, see *Section 4.6.4*).

```

    ]Number 42
2A

    ]Number 42 42
2A 2A

    ]Number 42 42 42
* Command Execution Failed: too many arguments

    ]Number 42 Fiona
2A 40

```

Changing the `Parse` variable again, this time from `'2S'` to `'2L'`, means that 2 arguments must be supplied; if more than this are supplied then the first argument is taken as specified and the rest are merged together to become the second argument (for more information on this, see *Section 4.6.5*).

```

    ]Number 42
* Command Execution Failed: too few arguments

    ]Number 42 42
2A 2A

    ]Number 42 42 42
2A Unrecognised Name

    ]Number 42 Fiona
2A 40

```

B.5 Example: Debugging a User Command

This example illustrates using the `JUDebug` user command to debug a namespace containing a user command group definition.

Three keyboard shortcuts for command codes are referred to in this example – `<TC>` (*Trace*), `<ED>` (*Edit*) and `<EP>` (*Escape*). The usual key combinations for these are operating-system-dependent.

Relevant key combinations on the Microsoft Windows operating system:

- `<TC>` is usually **Ctrl + Enter**
- `<ED>` is usually **Shift + Enter**
- `<EP>` is usually **Escape**

Relevant key combinations on the UNIX operating system:

- **<TC>** is usually **APLKey + Shift + Enter**
- **<ED>** is usually **APLKey + Enter**
- **<EP>** is usually **Escape**

Relevant key combinations on the macOS operating system:

- **<TC>** is usually **Ctrl + Enter**
- **<ED>** is usually **Shift + Enter**
- **<EP>** is usually **Escape**

A user command can be debugged by tracing through `SE . UCMD` (see *Section 3.3*). However, a more convenient method is to instruct the framework to suspend on the first line of the `Run` or `Help` function – tracing/debugging can then proceed from there. To do this, debugging mode must be switched on:

```
]UDebug on
Was OFF
```

If an error is encountered in debugging mode, execution of the user command is suspended rather than returning to the calling function.

When debugging is enabled, specifying a space followed by the `-` character at the end of the command opens the **Trace** window with the code suspended on `Run[1]`. For example, using the `number` namespace defined in *Section B.4* to hold the `AgeHex` group of user commands:

```
]Number 42 Andy
2A 51

]Number 42 Andy -
Run[1]
```

To progress through the `Run` function, enter the *Trace* command (**<TC>**).

You can now trace and debug the code in the namespace.

The **Trace** window shows that, in the `number` namespace, the `Parse` variable is set to `2S`. This means that the `Args` variable is a namespace. The namespace contains a number of variables, one of which is `Arguments`:

```
]Disp Args
SE.[Namespace]

Args.␣NL 2
Arguments
```

```
SwD
_1
_2

]Disp Args.Arguments
```

This shows that the `Arguments` variable is a vector comprising two character vectors.

Enter the *Edit* command (**<ED>**) to open the namespace definition in the **Edit** window and change the `Parse` variable from `'2S'` to `'2L'`. Save the changes and repeatedly enter the *Escape* command (**<EP>**) until you are no longer tracing through code. Then enter:

```
]Number 42 Andy 8 9 10 -
```

With the `Run` function suspended, enter:

```
]Disp Args.Arguments
```

This shows that the `Arguments` variable is still a vector comprising two character vectors. However, the second of the two character vectors now includes everything after the first argument in the call to the user command.

Press the **<ED>** key combination to open the namespace definition in the **Edit** window and change the `Parse` variable from `'2L'` to `'2S -true'`. The `'-true'` means that the parser now accepts a modifier called `-true` that does not accept a modifier value but can only be present or absent (see *Section 3.7.2*). Save the changes and repeatedly hit **<EP>** until you are no longer tracing through code. Then enter:

```
]Number 42 Andy -
Args.[]NL 2
Arguments
SwD
_1
_2
true
```

This shows an additional variable, `true`, created with the same name as the modifier that was included in the `Parse` variable. However, when calling the `]Number` user command, this on/off modifier was not specified. Therefore:

```
Args.true
0
```

To see the effect of calling the]Number user command with this modifier specified:

```
)reset  
]Number 42 Andy -true -  
Args.true  
1
```

Debugging mode is switched off using:

```
]UDebug off  
Was ON
```
