1 Introduction

HTMLRenderer is a built-in Dyalog object which provides a cross-platform mechanism for producing Graphical User Interfaces (GUIs), based on Hypertext Markup Language (HTML). As of Dyalog version 18.0 HTMLRenderer is available on Microsoft Windows, Apple macOS, and Linux (excluding the Raspberry Pi). Using HTMLRenderer, your application can use the same code to provide a consistent user interface across platforms.

HTMLRenderer is a built-in class, instances of which are created and managed using the Dyalog GUI framework functions `WC/WS/WG/NEW` and `DQ/NQ`. User interfaces are defined using HTML, which can, in turn, make references to code and data in a number of additional formats such as JavaScript to manage highly interactive content, Cascading Style Sheets (CSS) for both simple and sophisticated styling, and SVG, JPG or BMP for images.

On all platforms, the creation of an HTMLRenderer object causes APL to open a new window and run a copy of the Chromium Embedded Framework (CEF). HTMLRenderer manages the communication between your APL code and CEF.

In addition to fixing several issues, Dyalog APL version 18.0 introduces some new features for HTMLRenderer.

- More convenient UTF-8 support. The HTML property can now contain Unicode code points greater than 127 without additional translation or formatting. However, this is a potentially **breaking change** for applications written using earlier versions of HTMLRenderer. See [UTF-8 Support](#).
- Improved WebSocket support.
- An **ExecuteJavaScript** method which allows you to send JavaScript statements to be executed in the rendering window.
- The default behavior for the **InterceptedURLs** property has been changed such that, in many cases, it will be unnecessary to set **InterceptedURLs**.

The HTMLRenderer can be disabled by setting the `ENABLE_CEF` environment variable to 0; if `ENABLE_CEF` is not set or is set to 1 then the HTMLRenderer is enabled (the default).

On some platforms the HTMLRenderer and RConnect (the Dyalog R interface) both expect to run in the main thread. Attempting to run both in the same process may lead to APL terminating uncleanly; if you want to use RConnect set `ENABLE_CEF=0`. Attempting to create an instance of HTMLRenderer on a platform where `ENABLE_CEF` when `ENABLE_CEF` is 0 will cause a "LIMIT ERROR: The object could not be created" error to be signalled. See section 4, *Technical Overview* for more information on enabling the HTMLRenderer on various platforms.

1.1 Hello World

Below is a simple HTMLRenderer example. The first line defines the HTML body, and uses the `<h1>` (heading level 1) tag create the large, bolded, "Hello World" followed by more text containing some APL characters. The second and third lines define the size and coordinate system. The last line creates an HTMLRenderer using the HTML, Size and Coord properties:

```
html←'<h1>Hello World</h1>This is an αρ| page.'  
size←150 250  
coord←'ScaledPixel'  
'hr' ⎕WC 'HTMLRenderer' ('HTML' html)('Size' size)('Coord' Coord)
```

The resulting window on various platforms looks like:

Linux (Ubuntu)

macOS (Catalina)

Windows 10

Screenshots throughout this document will be captured from different platforms on different machines with different screen resolutions.

1.2 Other Resources

All HTML applications are based on an initial HTML document. Most modern HTML-based user interfaces will reference other resources, such as JavaScript and CSS files which contain code that can influence the way the base HTML is rendered, image files, and of course hyperlinks to other pages.

If the HTML contains references to other resources, the CEF will retrieve each one by making an HTTP request. Each request with a URL that matches a triggering pattern in `InterceptedURLs` will generate an `HttpRequest` event on the instance of `HTMLRenderer`, which can be directed to a callback function in APL. Requests with URLs that do not match a pattern in `InterceptedURLs` or that match a pattern with a 0 in the second column will cause the CEF to push the request out to the network and see whether an external server is able to service it. `InterceptedURLs` allows an APL application to decide how which content it wants to provide, and to what extent it wants to act as a portal for other services that will provide the rest of the data.

1.3 User Events

When a user submits an HTML form for processing, or a user interface component which is being managed by JavaScript code wishes to make a server request, this is also done by making an HTTP request. These requests will also be directed through the same `InterceptedURLs` mechanism. This makes it possible to develop interactive applications where your APL code is responding to user input, as well as providing the content of resources needed to render the UI.

1.4 Platform Variations

Under Microsoft Windows, `HTMLRenderer` objects can be used as children of normal `QWC` forms. Some properties such as `MinButton`, `MaxButton`, and `Sizeable` are not available on all platforms. See [Properties Available by Platform](#).

1.5 UTF-8 Support

UTF-8 is the default character set for HTML5. Prior to version 18.0, Unicode code points greater than 127 would need to be converted to their equivalent HTML entities. For instance, `ı` would need to be encoded as `⍁`. Version 18.0 removes this requirement by prepending a UTF-8 byte order mark (BOM) to the HTML content sent to CEF. Content that should not have the BOM prepended (for example, an image) should be sent as integer datatype 83. This is a **breaking change** from previous versions of `HTMLRenderer`.

1.6 Integration with the Dyalog GUI on Windows

The following code illustrates how HTMLRenderer objects can be used as children of normal `WC` forms under Microsoft Windows. By setting the `AsChild` property of an `HTMLRenderer` object to 1, we request that the `HTMLRenderer` window be embedded as a sub-form of another window.

```
'pco' WC 'dfns'
'f1' WC 'Form' 'Important Stuff' ('Coord' 'ScaledPixel') ('Size' 820 1100)
'f1.label1' WC 'Label' 'Primes < 100' (10 40)
'f1.primes' WC 'Grid' ('*' @ (0;pco) 10 10p100) ('Posn' 40 40)
f1.primes.(TitleHeight TitleWidth CellWidths Size)+0 0 25 (200 255)
'f1.label2' WC 'Label' 'Has the Large Hadron Collider destroyed the world yet?' (360 40)
'f1.areWeStillHere' WC 'HTMLRenderer' ('AsChild' 1) ('Posn' 390 40) ('Size' 400 500)
f1.areWeStillHere.URL+ 'http://hasthelargehadroncolliderdestroyedtheworldyet.com'
twitter+ '<a class="twittertimeline" href="https://twitter.com/dyalogapl">'
twitter+ '<Tweets by dyalogapl</a>'
twitter+ '<script async src="//platform.twitter.com/widgets.js" charset="utf-8"></script>'
'f1.twitter' WC 'HTMLRenderer' ('AsChild' 1) ('Posn' 40 570) ('Size' 750 500)
f1.twitter.HTML+twitter
```

The result after clicking on the "Tweets by dyalogapl" link can be seen below; a form that contains a Windows grid showing prime numbers between 1 and 100 as well as provides live feeds from two external sites. Note that no callbacks have been assigned; in this case the `HTMLRenderer` always goes to the network to satisfy requests for data.

2 Simple Examples

2.1 Render a SharpPlot chart

SharpPlot charts can be rendered as SVG which in turn can be visually rendered with HTMLRenderer.

```
)LOAD sharpplot  
saved...
```

```
'HR' □WC 'HTMLRenderer' ('Size' 75 50)  
HR.HTML←#.Samples.Sample.RenderSvg #.SvgMode.FixedAspect
```

2.2 An application with 2 Pages

The function on the next page creates a very simple application with 2 pages: A home page called main and another page called clicked which is displayed if the user follows a link. Initialise the application by calling myapp with an empty right argument; this will cause it to create a namespace containing all the resources, and then create an HTMLRenderer and set the URL property so that it navigates to the first page – and itself as the callback function.

If called with a non-empty argument, the function handles callbacks. It extracts the page name from the URL, which corresponds to a variable in the namespace and returns the value of that variable as the response to the request.

```

▽ r←myapp args;root;evt:url;size;coord;obj;op;int;sc;st;mime;hdr;data;meth;page
[1] A Serve up a small 2 page application
[2]
[3] A If you set the root to something other than http://dyalog_root/
[4] A then you need to use InterceptedURLs to indicate APL is to handle the request
[5] root←'http://dyalog_root/' A set the root, requests from CEF will start with this
[6]
[7] :If 0εargs A empty args means we're doing Setup
[8]
[9] A define the "app" in MyApp, 2 static HTML pages
[10] #.MyApp←⊞NS ''
[11] A HTML for the "main" page
[12] #.MyApp.main←'Hello APLers<br/>Click <a href="clicked">here</a>!'
[13] A HTML for the "clicked" page
[14] #.MyApp.clicked←'Thank you!<br/>Click <a href="main">here</a> to go back! '
[15] A whenever we get a request for a resource, call myapp (this function)
[16] evt←'Event' 'HTTPRequest' 'myapp'
[17] A set the initial URL to the "main" page
[18] url←'URL'(root,'main')
[19] A set some window parameters
[20] size←'Size'(150 300) ⋄ coord←'Coord' 'ScaledPixel'
[21] A and off we go...
[22] 'hr'⊞WC'HTMLRenderer'url evt size coord
[23]
[24] :Else A handle the HTTPRequest event
[25]
[26] (obj evt op int sc st mime url hdr data meth)+11targs
[27] A extract the page name
[28] page←(≠root)↓url
[29] A does the page exist?
[30] :If 2=#.MyApp.⊞NC page
[31] A set the HTTP status and text for a successful request
[32] (sc st)+200 'OK'
[33] A set the response data to the new page's HTML
[34] data←#.MyApp$page
[35] :Else
[36] A set the HTTP status and text for a failed (not found)
[37] (sc st)+404 'Not Found'
[38] data←'<h2>Page not found!</h2>'
[39] :EndIf
[40] A set the MIME type for the response
[41] mime←'text/html'
[42] A indicate that we've intercepted and handled this request
[43] int+1
[44] r←obj evt op int sc st mime url hdr data
[45] :EndIf
▽

```

After running

```
myapp ''
```

clicking the links will toggle between these two pages

2.3 A Form with a Button

Define a callback function:

```

▽ r←my_callback args;obj;evt;op;sc;st;mime:url;hdr;data;int;meth
[1]  A Our first HTTPRequest callback function
[2]  (obj evt op int sc st mime url hdr data meth)←11fargs
[3]  int←1                               A indicate we've intercepted this call
[4]  (sc st mime)←200 'OK' 'text/html' A HTTP success code
[5]  url+hdr←''                             A no url or headers
[6]  data←'<title>Thank You!</title><h2>Thank you!<h2>' A response Data
[7]  r←(obj evt op int sc st mime url hdr data)
▽

```

Now, define a form and set up the callback:

```

'hr' □WC 'HTMLRenderer' '<title>Hello</title><p>Hello, <b>APLers!</b></p>'
hr.(Coord Size Posn)←'Pixel'(200 450)(20 20)
hr.HTML,←'<form action="#"><button>Click Me!</button></form>'
hr.onHTTPRequest←'my_callback'

```

The form should look like this:

If you click on the button, the content should be replaced:

2.4 Using HRUtils with HTMLRenderer

HRUtils is a utility namespace provided with Dyalog APL v18.0 and later. It contains classes and functions to streamline handling of HTMLRenderer's HTTPRequest events.

Another utility namespace, HttpUtils, which was released with Dyalog v16.0 was designed to provide a more consistent interface for managing HTTP requests whether using Conga or HTMLRenderer. Of the two, we recommend using HRUtils for HTMLRenderer applications.

Both HRUtils and HttpUtils are distributed in the /Library/Conga/ folder in your Dyalog installation and can be loaded using the SALT Load command. Both of the following statements will load HttpUtils, though the latter is suitable for running under program control.

```
]load HRUtils
⊞SE.SALT.Load 'HRUtils'
```

HRUtils is maintained in the Dyalog GitHub repository found at <https://github.com/Dyalog/library-conga>. There you can see the revision history and you may participate in the development community by reporting issues and by posting questions and suggestions.

The following example shows a simple HTML form with 2 input fields and a submit button. The callback is processed using the HTTPRequest class found in HRUtils.

```
▽ r←SimpleForm args;evt;html;req;resp;who
[1] :If 0εargs A Setup
[2]   html←'<title>A Simple Form</title>'
[3]   html,←'<form method="post" action="SimpleForm"><table>'
[4]   html,←'<tr><td>First: </td><td><input name="first"/></td></tr>'
[5]   html,←'<tr><td>Last: </td><td><input name="last"/></td></tr>'
[6]   html,←'<tr><td colspan="2"><button>Click Me</button></td></tr>'
[7]   html,←'</table></form>'
[8]   evt←'Event' 'HTTPRequest' 'SimpleForm'
[9]   'hr'⊞WC'HTMLRenderer'('HTML'html)('Coord' 'ScaledPixel')('Size'(200 400))evt
[10] :Else A handle the callback
[11]   req←#.HRUtils.Request args           A create a request from the callback args
[12]   who←req.Get''first' 'last'           A retrieve from the form data
[13]   who←ε' ',who
[14]   req.Response.Content←'<h2>Welcome',who,'!</h2>' A set the content for the response
[15]   r←req.Respond A return the formatted response
[16] :EndIf
▽
```

Running SimpleForm '' displays the form. After filling in the form and clicking the button, SimpleForm is called again as the callback function for the HTTPRequest event, but this time args is non-empty and the callback portion lines [11–15] are executed.

```
[11]   req←#.HttpUtils.Request args           A create a request from the callback
args
```

The Request function creates an instance of the HttpRequest class from the event message, parsing the message data and extracting the various elements into a more useful and accessible format.

```
[12]         who←req.Get''first' 'last'           A retrieve from the form data
```

The `HttpRequest` class has extracted the HTML form field values into `FormData` which can be accessed using the `HttpRequest`'s `Get` method. The values are retrievable by their field names in the HTML form, in this case `'first'` and `'last'`. Refer to lines [4-5] in `SimpleForm` to see where the field names were originally assigned.

```
[13]         who←ε' ', "who"
[14]         req.Response.Content←' <h2>Welcome',who,'!</h2>' A set the content for
the response
```

We now set `Content` in the response to be our new content for the page. The default content type is `'text/html'`, but other content types can be specified as appropriate for your application.

```
[15]         r←req.Respond A return the formatted response
```

Finally, the `Respond` method formats and populates a result appropriate for the callback and our friendly message is displayed.

3 Generating HTML

Dyalog provides a number of tools to help you generate HTML.

SharpPlot

The SVG data produced by the RenderSVG method can be assigned directly to the HTML property of an HTMLRenderer object. The CEF accepts SVG in place of HTML and is able to render it without further intervention. You can also use the various Save... functions in SharpPlot to save graphs in SVG or other formats, and link to them using an HTML `img` tag.

DUI – Dyalog User Interface Utility Library

DUI is an evolving library to assist in creating HTML content. Originally a part of MiServer, DUI is designed to enable you to create HTML that can be run locally with HTMLRenderer or on the net with MiServer – without changing your code. DUI contains APL code that is able to generate HTML, CSS and JavaScript based widgets based on the HTML5 widget set, Syncfusion controls (which are bundled with Dyalog), jQueryUI and other third-party widgets. DUI is currently available from the Dyalog GitHub repository at <https://github.com/Dyalog/DUI>. To use DUI, you will need to download or clone the repository. To illustrate the DUI style of coding, the following code should produce a form with two input fields and a button:

```
]load /path_to_DUI/DUI
DUI.Initialize
page←NEW Page
page.Add _.title 'Hello World!'
page.Add _.Style 'body' ('font-family' 'Verdana')
page.Add _.h3 'Hello World!'
form←page.Add _.Form
'fn' form.Add _.Input 'text' 'Drake' 'First Name: '
'ln' form.Add _.Input 'text' 'Mallard' ' :Last Name' 'right'
p1←'p1' form.Add _.p ''
b1←'b1' form.Add _.Button 'Press Me'
b1.style←'color:purple'
page.Size←200 600
page.Run
```

4 Technical Overview

The HTML Renderer is implemented using the Chromium Embedded Framework (CEF); for more information on CEF visit

https://en.wikipedia.org/wiki/Chromium_Embedded_Framework.

4.1 HTMLRenderer on non-Windows platforms

The HTMLRenderer on non-Microsoft Windows platforms is an X-Windows application. As such there are a set of pre-requisites that are needed on the operating system instance on which the Dyalog interpreter is running (this in X-Windows terms is the server) and a set of pre-requisites that are needed on the operating system instance where the output will be displayed (in X-Windows terms the client). In most cases these two sets of functionality run in the same operating system instance. However, this means that a typical non-GUI installation of a Linux distribution is unlikely to allow you to create an HTMLRenderer object even if you are trying to display it elsewhere by setting the DISPLAY variable appropriately.

For Linux, we have tried creating the HTMLRenderer on a number of common distributions and versions. See <https://forums.dyalog.com/viewtopic.php?f=20&t=1505> which details what pre-requisites are needed for the HTMLRenderer on those distributions.

If you get a LIMIT ERROR when attempting to create an HTMLRenderer object and you are either using a distribution/version that is not in the list below, or have ensured that you have met the pre-requisites mentioned below, then run the following expression from within Dyalog APL:

```
)sh ldd $DYALOG/lib/htmlrenderer.so | grep found
```

This should list any missing pre-reqs. Please let Dyalog know so that we can update the supported versions matrix.

Note: As of 2019-05-10, Dyalog does not support the HTMLRenderer being used on a Virtual Machine in which Linux has been installed. We are attempting to understand why this does not run reliably, but the issue may be intractable.

4.2 CEF/Chromium Command Line Switches

There are very many command line switches that can be used with CEF to alter behavior, help debugging or aid in experimenting. These switches need to be set using the `-cef` or `-cef_all` options when Dyalog APL is started. If you're setting a single CEF command line switch, you can use:

```
-cef --command-line-switch
```

If you're setting more than one CEF command line switch, then you either need to prefix each on with `-cef` or place them at the end the Dyalog command line preceded by `-cef_all` as in:

```
-cef --command-line-switch1 -cef --command-line-switch2  
-cef_all --command-line-switch1 --command-line-switch2
```

Note that the command line switches begin with a double dash (`--`).

One common command line switch is to enable a remote debugging port for CEF so that you can attach a browser to CEF and open the Developer Tools Console.

```
-cef --remote-debugging-port=12345
```

Then open a browser and navigate to the address of the computer where HTMLRenderer is running and the port indicated by `--remote-debugging-port`.

A fairly comprehensive list of command line switches can be found at <https://peter.sh/experiments/chromium-command-line-switches/>.

5 HTMLRenderer Reference

This section highlights specific aspects the HTMLRenderer. For a complete description of the Properties, Events and Methods for the HTMLRenderer object, please refer to the object reference guide at <http://help.dyalog.com/18.0/Content/GUI/Objects/HTMLRenderer.htm>.

5.1 Properties

As HTMLRenderer is an object in the Dyalog GUI framework, it has many of the expected properties for a `GUI` control. The properties for HTMLRenderer are found in table 1, with properties specific to HTMLRenderer highlighted in red.

Table 1. HTMLRenderer properties

Type	HTML	Posn
Size	URL	Coord
Border	Visible	Event
Sizeable	Moveable	SysMenu
MaxButton	MinButton	IconObj
Data	Attach	Translate
KeepOnClose	AsChild	InterceptedURLs
CEFVersion	Caption	MethodList
ChildList	EventList	PropList

5.2 Properties Available by Platform

Not all properties are available on all platforms. The table below illustrates the properties that vary by platform. Properties listed as N/A are specific to Windows and do not have equivalent counterparts under macOS or Linux.

Table 2. HTMLRenderer properties by platform

Property	Windows	macOS	Linux
Type	Y	Y	Y
HTML	Y	Y	Y
Posn	Y	Y	Y
Size	Y	Y	Y
Coord	Y	Y	Y
Border	Only when using AsChild	N/A	N/A
Visible	Y	Y	Y
Sizeable	Y	Y	N
Moveable	N	N	N
SysMenu	Y	N/A	N

MaxButton	Y	N	N
MinButton	Y	Y	N
IconObj	Y	N/A	N/A
Attach	Only when using AsChild	N/A	N/A
Translate	Classic Only	N/A	N/A
KeepOnClose	Y	Y	Y
AsChild	Y	N/A	N/A
CEVersion	Y	Y	Y
Caption	Y	Y	Y

5.3 Properties With Behavior Specific to HTMLRenderer

The properties are presented here in an order intended provide context for how certain properties interrelate.

HTML

The `HTML` property is the payload to be sent to CEF from APL. In general, it will be the HTML content that will be rendered in the HTMLRenderer window. But it could also be other content like an image file, a JavaScript file, or a CSS stylesheet. When sending HTML, the data is assumed to be UTF-8 and you can simply assign your character vector to the property. When the content is not UTF-8, like an image, you will need to send the data as single-byte integer (datatype 83).

URL

The `URL` property is a character vector representing the "root" URL of the object. If not specified, 'http://dyalog_root/' is the implied value of `URL`. If subsequent requests for resources are received via the `HTTPRequest` event, the `URL` element of the callback arguments can be examined to see if it begins with the "root". If so, the content is intended to be provided locally by your application, otherwise, it should be retrieved from the `URL` element of the argument.

Relationship between the HTML and URL properties

In general, either the `HTML` or `URL` property will be specified, but not both. If `URL` is non-empty, it will take precedence over `HTML`, even if the resource specified by the `URL` is not found. If neither `HTML` or `URL` is specified, HTMLRenderer will trigger an `HTTPRequest` event for the URL 'http://dyalog_root/'.

InterceptedURLs

The `InterceptedURLs` property is a 2-column matrix what action HTMLRenderer will take on an `HTTPRequest` or a `WebSocketUpgrade` request. The first column contains wild-carded character vectors containing URL patterns to match. The second column is an integer where:

- 0 indicates HTMLRenderer should attempt to retrieve the resource over the net.
- 1 indicates HTMLRenderer should trigger an `HTTPRequest` event for a URL matching the corresponding pattern
- 2 indicates that a `WebSocketUpgrade` event triggered a matching URL should be manually verified.

`InterceptedURLs` may contain any number of rows and the first matching pattern for a

requested URL will determine how the request is routed. URLs matching the pattern `'*://dya log_root/*'` or that have a 1 in the second column will trigger an HTTPRequest event; all other URLs will be attempted to be retrieved over the net. The default value for `InterceptedURLs` is `0 2ρ '*' 0`.

Examples:

The following will trigger an HTTPRequest event for all requested URLs

```
InterceptedURLs ← 1 2ρ '*' 1
```

The following will attempt to retrieve from the net URLs containing `'.dya log.com'` and trigger an HTTPRequest event for all other requested URLs

```
InterceptedURLs ← 2 2ρ '*.dya log.com*' 0 '*' 1
```

AsChild

This property has an effect only on Microsoft Windows platforms.

The `AsChild` property is a Boolean indicating how the HTMLRenderer object should be treated. Possible values are:

- 1 – the HTMLRenderer object should be treated as a child of its parent object.
- 0 – the HTMLRenderer object should be treated as a top level object similar to how a Form object is treated.

The default is 0.

CEFVersion

Returns version information about the CEF. This is used primarily for support and debugging purposes.

Caption

Note that the caption appearing in the title bar of the HTMLRenderer window can be set either with the `Caption` property or by a `<title>` element within the HTML for the page. If both are set, the `<title>` element takes priority. For example:

```
html←'<title>Title Wins!</title>Test'  
'hr' WC 'HTMLRenderer'('HTML' html)('Caption' 'Caption Wins!')('Size' (10 20))
```

It is recommended that you use `<title>` to control the caption on the title bar element because changes to the HTML `<title>` will be reflected in the `Caption` property. However, the converse is not true – changes to the `Caption` property are not reflected in the document's `<title>` element.

5.4 Events

The events for HTMLRenderer are found in table 3, with events specific to HTMLRenderer highlighted in red.

Table 3. HTMLRenderer events

Close	Create	HTTPRequest
WebSocketUpgrade	WebSocketReceive	WebSocketClose
WebSocketError	DoPopup	SelectCertificate

5.5 Events Specific to HTMLRenderer

HTTPRequest

An `HTTPRequest` event is raised whenever content is required that is not provided by the HTML property. This could be generated by a form submission, clicking on a hyperlink, an AJAX request or a link to a resource like a stylesheet, image or JavaScript file.

The event message reported as the result of `DDQ` or supplied as the right argument to your callback function, is a 11-element vector as described in table 4.

NOTE: the event message only had 10 elements in version 16.0. Application code should not assume a specific length for this, or indeed any other event messages.

Table 4. Explanation of the 11-element vector `HTTPRequest` event message

[1]	HTMLRenderer object name or reference
[2]	Event name 'HTTPRequest' or 840
[3]	Constant 'ProcessRequest'
[4]	0
[5]	0
[6]	''
[7]	''
[8]	Requested URL
[9]	HTTP Request Headers
[10]	HTTP Request Body
[11]	HTTP Method - Typically this will be 'GET' or 'POST'.

When preparing a response, certain elements of the event message need to be updated. Specifically:

[4]	Set to 1 to update the rendering window based on the updated elements of the event arguments.
[5]	Set to the HTTP status code for the response. Success is indicated by code 200.
[6]	Set to the HTTP status message for the response. Success is indicated by the message 'OK'.
[7]	Set to the MIME type of the response. If not specified, 'text/html' is assumed.
[9]	Set to any HTTP response headers necessary for the response.

[10]	Set to the body of the response. If the body is not UTF-8 text, convert it to single-byte integer (datatype 83).
------	--

WebSocketUpgrade, WebSocketReceive, WebSocketClose, WebSocketEnd
Please refer to Section 6, *Websocket support* for more information.

DoPopup

A DoPopup event is raised whenever the CEF client executes a request for a new window to be opened. This would typically be when a link element specifies a target attribute of "_blank", as in:

```
<a href="http://www.dyalog.com" target="_blank">
```

When a DoPopup event occurs, the application should inspect the request and open another HTMLRenderer as appropriate.

Elements of the DoPopup event message

[1]	HTMLRenderer object name or reference
[2]	Event 'DoPopup' or 848
[3]	The requested URL
[4]	7-element vector of requested window attributes

The attributes vector contains requested attributes for the new window, however HTMLRenderer currently has no mechanism to use this information.

SelectCertificate

A SelectCertificate event is raised whenever a resource is requested from a server that requires a certificate for security. The available certificates are in element [7] of the callback arguments. The application should select one of the certificates and set element [3] to its origin-0 index in the Certificates element.

Elements of the SelectCertificate event message

[1]	HTMLRenderer object name or reference
[2]	Event 'SelectCertificate' or 848
[3]	Certificate index (result only)
[4]	Host address
[5]	Host port
[6]	'is proxy'
[7]	Certificates (see below)

Certificates is a vector of namespaces, each of which represents a certificate and contains the following variables:

Name	Description
DER	The DER-encoded certificate
Subject	A namespace containing variables CommonName, CountryName and DisplayName for the certificate subject.

Issuer	A namespace containing variables CommonName, CountryName and DisplayName for the certificate issuer.
SerialNumber	Character vector certificate serial number

5.6 Methods

The methods for HTMLRenderer are found in table 5, with events specific to HTMLRenderer highlighted in red.

Table 5. HTMLRenderer methods

Detach	PrintToPDF	WebSocketSend
WebSocketClose	ShowDevTools	Wait
ExecuteJavaScript		

5.7 Methods Specific to HTMLRenderer

WebSocketSend, WebSocketClose

Please refer to section 6, WebSocket Support, later in this document.

ShowDevTools

The ShowDevTools method is used to open or close the Chromium Developer Tools console. Its only argument is a Boolean as in:

```
'hr' WC 'HTMLRenderer'
hr.ShowDevTools 1  A open developer tools
hr.ShowDevTools 0  A close developer tools
```

Chromium Developer Tools is a very useful debugging and inspection utility.

ExecuteJavaScript

The ExecuteJavaScript method is used send a character vector containing JavaScript code to CEF to be executed. At present this is a one-way communication and no result from the executed code is sent back to APL.

Example:

```
'hr' WC 'HTMLRenderer'
hr.ExecuteJavaScript 'alert("Hello")'
```

6 Websocket support

6.1 Websocket Overview

In a typical HTTP application, all communication originates from the client which sends requests to the server which in turn sends back a response. When an application wanted to "push" information from the server to the client, the typical way to fake this was to have the client periodically poll the server so the server could send back any information that it had to offer. With the use of websockets, true asynchronous, bi-directional transmission between the client and server is possible.

HTMLRenderer presents a straightforward API to use websockets. A typical scenario would look something like this:

1. The client initiates an HTTP "upgrade" request to the server. After some validation and handshaking with the server, the websocket is established. With HTMLRenderer, the validation and handshaking are currently done behind the scenes and by the time you receive a `WebSocketUpgrade` event, the websocket already established.
2. Once the websocket is established, either the client or the server can send information which will trigger a "receive" event on the other end. No response is expected as a part of the websocket protocol. Whatever response you send (or don't) is up to your specific application.
3. Either side can close the websocket.
4. Websocket error events may be triggered when an unexpected error, like disruption in the connection, occurs.

JavaScript in the CEF client		HTMLRenderer in the workspace
<code>ws = new websocket(url);</code> Initiate the request	→	<code>WebSocketUpgrade</code> event The websocket is established
<code>ws.send("message");</code>	→	<code>WebSocketReceive</code> event
<code>ws.onmessage</code> event	←	<code>WebSocketSend</code> method
<code>ws.close()</code>	→	<code>WebSocketClose</code> event
<code>ws.onclose</code> event	←	<code>WebSocketClose</code> method
<code>ws.onerror</code> event is triggered when there is some error like the connection going down		<code>WebSocketError</code> event occurs when there is some error like the connection going down

The client may request multiple upgrades resulting in multiple websockets, each with its own unique id.

WebSockets require JavaScript in the client to function.

6.2 WebSocket Events

WebSocketUpgrade

This event is triggered when the client attempts to upgrade the HTTP connection to use the WebSocket protocol. The event message is a 6-element vector containing:

Elements of the WebSocketUpgrade event message

[1]	HTMLRenderer object name or reference
[2]	Event 'WebSocketUpgrade' or 841
[3]	Character vector WebSocket ID
[4]	Requested URL
[5]	Request/Response headers
[6]	'auto' or 'manual' depending on InterceptedURLs setting of 1 or 2 respectively for the pattern that matched the URL in element [4]

The protocol for establishing the connection is defined by InterceptedURLs and is reported by the 6th element of the event message.

If the element matches 'auto', the handshake is handled internally and this event is reported when the connection has already been made. In this case the result, if any, of the callback function is ignored.

If the element matches 'manual', a callback function for WebSocketUpgrade is mandatory and is responsible for completing (or denying) the connection. This is achieved by setting the 5th element (headers) of the event message to indicate an appropriate positive or negative response to the request and returning the entire event message as its result. Each header must be followed by CRLF. If a valid response is not generated in this way, the connection will time-out causing a WebSocketError event.

The WebSocket ID is used when sending data to the client using the WebSocketSend method or when closing the WebSocket with the WebSocketClose method.

WebSocketReceive

This event is triggered when the client sends data over the WebSocket. The result, if any, of the callback function is ignored. ShowDevTools method is used to open or close the Chromium Developer Tools console. Its only argument is a Boolean as in:

Elements of the WebSocketReceive event message

[1]	HTMLRenderer object name or reference
[2]	Event 'WebSocketReceive' or 842
[3]	Character vector WebSocket ID
[4]	Data from the client
[5]	Boolean - 1 indicates the entire message has been received, 0 indicates there is more data to follow.
[6]	Datatype - 1 indicates character (UTF-8), 2 indicates numeric in the range $\bar{1}28\bar{1}27$

WebSocketError

This event is triggered when an error occurs on the WebSocket. The result, if any, from the callback function is ignored.

Elements of the WebSocketError event message

[1]	HTMLRenderer object name or reference
[2]	Event 'WebSocketError' or 844
[3]	Character vector WebSocket ID
[4]	Character vector error message

WebSocketClose

This event is triggered when the client closes the WebSocket. The result, if any, from the callback function is ignored.

Elements of the WebSocketClose event message

[1]	HTMLRenderer object name or reference
[2]	Event 'WebSocketClose' or 843
[3]	Character vector WebSocket ID
[4]	Integer status code. 1000 indicates normal closure
[5]	Character vector reason

6.3 WebSocket Methods

WebSocketSend

Use this method to send data to the client over the WebSocket. The argument can be a 2, 3 or 4-element vector.

Elements of the WebSocketUpgrade method argument

[1]	Character vector WebSocket ID
[2]	Data to send - either character (UTF-8) or integer vector
[3]	FIN flag - 1 indicates the message is complete, 0 indicates there is more data to come. This is not currently supported by CEF and should always be 1.
[4]	Datatype - 1 for character (UTF-8) data, 2 for binary (numeric) data in the range $\bar{128-255}$ which maps to 128-255, 0-255 in the client, or 0 to indicate continuation of previous message fragment.

The WebSocket protocol provides for messages to be sent in multiple fragments where the FIN flag is set to 0 for all but the last fragment. Currently CEF does not support fragmented messaging, but we include the FIN flag for possible future expansion.

The integer datatype range may seem a bit strange. It was implemented this way so that the user could conserve space by using single-byte integers (datatype 83) in the range $\bar{128-127}$, whereas some might find it more convenient to use the range 0-255. In either case both ranges translate to value 0-255 in the client.

WebSocketClose

This event is used to close the WebSocket from APL triggered when the client closes the WebSocket.

Elements of the WebSocketClose method arguments

[1]	Character vector WebSocket ID
[2]	Integer status code. 1000 indicates normal closure
[3]	Character vector reason (max length 123 bytes)

6.4 WebSocketSample function

The code necessary to demonstrate HTMLRenderer's WebSockets is larger than can be presented conveniently here. We have provided a sample function, `WebSocketSample.dyalog` found in the Dyalog Samples repository at

<https://raw.githubusercontent.com/Dyalog/Samples/master/HTMLRenderer/WebSocketSample.dyalog>.

Once you've loaded `WebSocketSample`, you can start it by running

```
WebSocketSample ''
```

From there you can click "Toggle Instructions" to see instructions.

Clicking "Open" will create a WebSocket. Once a WebSocket is created, you can enter text in the input area and click "Send". When you create a WebSocket using "Open", `WebSocketSample` defines a `Send` function in your workspace that you can then use to send data from APL to CEF as in

```
Send 'Hello from APL!'
```

The event message elements for every handled WebSocket event are displayed in your APL session. Every event handled by CEF is displayed in the output (log) area of the page.

7 HRUtils

7.1 Overview

HRUtils is a namespace that contains utilities for working with HTMLRenderer's HTTPRequest event. The steps to use HRUtils are as follows:

Within your callback function:

1. **Initialize**
When you receive an HTTPRequest event, call `HRUtils.Request`, passing the 11-element event message as its right argument

```
req←#.HRUtils.Request evtMsg
```

This creates an instance of a class called `HttpRequest` which in turn parses the elements of the event message and creates several conveniently accessible fields.
2. **Process**
Examine/use the data in the fields of `req` to process the request as appropriate. For example, use the `Get` method to retrieve data elements passed in the request:

```
who←req.Get''fname' 'lname' A retrieve 2 fields
```

Or check the `Uri` field to see what resource is being requested.
3. **Compose**
If the requested resource is a file, you can set the `FileName` field of the response:

```
req.Response.FileName←'c:/images/duck.png'  
'content-type' req.SetHeader 'image/png'
```

Or, if appropriate, compose the HTML for your response:

```
req.Response.Content←'Hi',ε' ', 'who
```
4. **Respond**
Then return the result of `req.Respond` as the result of your callback function.

```
r←req.Respond
```

HRUtils will take care of properly formatting and assigning the appropriate elements of the response.

7.2 HRUtils.HttpRequest class

The fundamental unit of work for HRUtils is the `HttpRequest`.

HttpRequest Fields

Method	The HTTP method for the request (generally 'get' or 'post')
Uri	The URI (URL) for the requested resource
Headers	2-column matrix of [;1] header names, [;2] header values
QueryData	2-column matrix of [;1] names, [;2] values of parameters (if any) passed in the query string of the request

FormData	2-column matrix of [;1] names, [;2] values of form fields either passed in the body of the request, or in the case of a 'get' Method, this is a copy of QueryData
Cookies	2-column matrix of [;1] names, [;2] values of cookies passed with the request
Response	An instance of the HttpResponse class created using elements of the event message
HTMLRendererArgs	A namespace containing the original event message elements

HttpRequest Methods

GetHeader	value←req.GetHeader 'name' return the value of the header named 'name' or '' if such a header doesn't exist.
Get	value←table req.Get 'name' return the corresponding value for 'name' or '' if name does not exist. table can be any of Headers, QueryData, FormData, or Cookies
Respond	callbackResult←req.Respond convert the Response instance into a format acceptable for the result of the HTTPRequent event callback

7.3 HRUtils.HttpResponse class

The HttpResponse contains what is sent back to CEF in response to the request.

HttpResponse Fields

HttpStatus	The integer HTTP status for the response 200 is success
HttpStatusText	The character HTTP status message for the response 'OK' is success
HTMLRenderArgs	A namespace containing the original event message elements (same as HttpRequest)
FileName	If the requested resource is a file, assign FileName to the actual file name.
Content	If the requested resource is not a file, compose your response data and assign it to Content.
Headers	2-column matrix of [;1] names, [;2] values of cookies to be sent with the response
Cookies	A vector of instances (if any) of the Cookie class representing cookies that are to be set in the client.

HttpResponse Methods

AddHeader	'name' req.Response.AddGetHeader 'value' Add a name/value pair to the response headers unless a header of the same name already exists.
-----------	--

AddCookie	<pre>req.Response.AddCookie arg arg is either - A character vector representing a formatted cookie string - A 2-7 element vector of Name - cookie name Value - cookie value Expires - cookie expiration datetime Domain - hosts allowed to see the cookie Path - path that must exist for cookie to be sent Secure - cookie may only be sent using HTTPS HttpOnly - cookie cannot be read by JavaScript</pre>
Respond	<pre>callbackResult←req.Response.Respond convert the Response instance into a format acceptable for the result of the HTTPRequet event callback req.Respond is essentially the same thing, but more convenient (less typing) to call</pre>

7.4 HRUtils.Cookie class

The fundamental unit of work for HRUtils is the HttpRequest. See <https://developer.mozilla.org/en-US/docs/Web/HTTP/Cookies> for more information on cookies

Cookie Fields

Name	The name of the cookie (required)
Value	The value of the cookie (required)
Expires	The TS format expiration (optional)
Domain	Hosts allowed to see this cookie. (optional)
Path	Path that must exist for this cookie to be sent. (optional)
Secure	Boolean indicating this cookie may only be sent using HTTPS (optional)
HttpOnly	Boolean indicating that this cookie cannot be read by JavaScript. (optional)

7.5 HRUtils Utility Functions

There are several utility functions HRUtils to aid in parsing and formatting response data.

```
r←{cpo} Base64Decode vec      - decode a Base64 encoded string
r←{cpo} Base64Encode vec     - Base64 encode a character vector, or
                              an integer (DR=83) vector
```

cpo - optional left argument (for code points only), is useful for encoding raw data like images.

Both Base64Decode and Base64Encode assume that the data is UTF-8. (setting cpo defeats this) This is useful for exchanging APL code and foreign characters.

Examples:

```
Base64Encode 'αρλ'           A use default UTF-8
1 Base64Encode NREAD -1 83 -1 A where a .png file is tied to -1
```

```
r←UrlDecode vec          - decodes a URL-encoded character vector  
r←{name} UrlEncode arg - URL-encodes string(s)
```

arg can be one of

- a simple character vector (name may be supplied as left argument)
- a vector of character vectors of name/value pairs
- a 2-column matrix of name/value pairs
- a namespace containing named variables

name - optional left argument name

Both UrlDecode and UrlEncode assume that the data is UTF-8

Examples:

```
UrlEncode 'Hello World!'  
Hello%20World%21
```

```
UrlEncode 'phrase' 'Hello World!'  
phrase=Hello%20World%21
```

```
UrlEncode 'company' 'dyalog' 'language' 'APL'  
company=dyalog&language=APL
```

```
UrlEncode 2 2ρ'company' 'dyalog' 'language' 'APL'  
company=dyalog&language=APL
```

8 Running HTMLRenderer under a Windows Runtime Application

To run HTMLRenderer under a Windows runtime interpreter (dyalogrt.exe) you should:

1. Create your runtime environment as described in the Dyalog for Microsoft Windows Installation and Configuration Guide
2. Copy the following files from the Dyalog installation folder into the same folder as the dyalogrt.exe:

```
htmlrenderer.dll
cef.pak
cef_100_percent.pak
cef_200_percent.pak
cef_extensions.pak
cef_sandbox.lib
chrome_elf.dll
d3dcompiler_43.dll
d3dcompiler_47.dll
devtools_resources.pak
icudtl.dat
libEGL.dll
libGLSv2.dll
libcef.dll
libcef.lib
locales
natives_blob.bin
snapshot_blob.bin
swiftshader
v8_context_snapshot.bin
```

9 Resources and References

The Dyalog webinar "*Something Old, Something New & Something Experimental*" includes a discussion and demonstration of the HTMLRender; it can be viewed at <https://dyalog.tv/webinar>.

Code samples can be copied-and-pasted from an HTML version of this document at <http://docs.dyalog.com/18.0/HTMLRender User Guide.htm>.

10 Change History

This section details the changes made to HTMLRenderer by release of Dyalog APL.

Version 18.0

This version provides:

- More convenient UTF-8 support. The HTML property can now contain Unicode code points greater than 127 without additional translation or formatting. However, this is a potentially **breaking change** for applications written using earlier versions of HTMLRenderer. See [UTF-8 Support](#).
- Improved WebSocket support.
- An **ExecuteJavaScript** method which allows you to send JavaScript statements to be executed in the rendering window.
- The default behavior for the **InterceptedURLs** property has been changed such that, in many cases, it will be unnecessary to set **InterceptedURLs**.

Version 17.1

This version provides:

- Support for websockets, allowing asynchronous, bi-directional communication between the APL session and the CEF client window.
- A **DoPopup** event that is triggered when the CEF client issues a request for a new window.
- A **SelectCertificate** event that is triggered when the CEF client issues a request for a resource that requires a certificate.
- A **ShowDevTools** method that will toggle the visibility of the Chromium Developer Tools to inspect and debug from the CEF client.
- Support for several **WC** properties including **Caption**, **SysMenu**, **MinButton**, **MaxButton**, **Sizeable** and **Moveable**. Some properties may not be available on a particular platform because that platform does not have underlying support for the property; setting such a property will have no effect, nor will it cause an error.
