## Chapter 1:

## Introduction

## Key Features

Dyalog APL Version 14.0 provides the following new features, enhancements and changes:

## Performance Improvements

Version 14.0 includes a considerable amount of research and development work designed to substantially improve speed of execution. See Performance Improvements on page 14.

## Language Enhancements

## New Language Features

- New terminology is introduced in Version 14.0 to describe sub-arrays of an array as cells. This terminology is used to describe the workings of the new Rank $\left({ }^{\circ}\right)$ and Key $\left(⿴_{0}\right)$ operators, the function Tally $(\neq)$, and the extension to dyadic Iota ( 2 ). See Cells and Sub-arrays on page 55.
- New Rank operator $\%$. See Rank on page 69
- New Key operator 目. See Key Operator on page 20.
- New function Tally $\not \equiv$. See Tally on page 57
- Function Trains. See Function Trains on page 19.

## New l-Beam Features

- A function is provided to support WPF data binding. See Data Binding on page 112.
- A function is provided to perform fast index-of operations on inverted table structures. See Inverted Table Index Of on page 103.
- A function is provided to obtain the current type of an array without it being squeezed first. See Unsqueezed Type on page 105.
- A function is provided to compress and decompress vectors of short integers. See Compress Vector of Short Integers on page 106.
- A function is provided to serialise and de-serialise an array. See Serialise/Deserialise Array on page 108.
- A function is provided to update the function timestamp and user. See Update Function Time Stamp on page 110.
- A function is provided to affect fine control over memory allocated to the workspace. See Specify Workspace Available on page 111.
- A function is provided to flush the Session caption. See Flush Session Caption on page 118.
- A function is provided to close all windows. See Close All Windows on page 122.
- A function is provided to set workspace save options. See Set Workspace Save Options on page 120.

## Extensions

- Dyadic $\imath$ has been extended to matrices and higher-rank arrays. See Index Of on page 21 .
- Mix ( $\uparrow \omega$ if $\square \mathrm{ml}<2 ; \supset \omega$ if $\square \mathrm{ml} \geq 2$ ) has been extended. See Mix on page 22.
- The APL2-compatible version of Mix ( $\supset \omega$ when $\square \mathrm{ml} \geq 2$ ) has been extended. See Mix With Axis on page 23.
- Monadic operators may now be named and assigned. See Rationalisation of Monadic Operators on page 24.
- Dyadic operators may now be bound with their right arguments to form monadic operators. See Right Operand Currying on page 25.
- Options for DXML may now be specified using the Variant operator ©. This becomes the recommended approach, although the use of the optional left argument will be retained for backwards compatibility. See XML Convert on page 86 .
- Roll can now generate random numbers in the range 0-1. See Roll on page 100.
- Table (monadic ;) may now be used in selective assignment.
- DRL has been extended to initialise the random number generator with a random seed. See Random Link Extension on page 26.

## Component File System Improvements

- Data in component files may now be compressed to improve performance when file access is slow. See Compressed Components on page 30.
- File properties may now be set when the file is created using a function derived from DFCREATE and the Variant operator 日. See File Create and Variant on page 31.
- DFREAD can now read multiple components. See File Read on page 29.
- Options for DFCHK may now be specified using the Variant operator (recommended) instead of using its optional left argument. See File Check and Variant on page 32.

## IDE Enhancements

- The system now generates a SessionPrint event when a value is about to be displayed in the Session. This event is used by the two new user commands described below. For further details, see SessionPrint on page 123.
- Jboxing user command optionally causes arrays displayed in the Session to be drawn in boxes to display their structure. See lboxing on page 35.
- Jrows user command controls how rows in multi-row output to the Session are displayed. See Jrows on page 36 .
- New Editor feature to align comments. See Aligning Comments on page 36.
- New Editor toolbar buttons. See New Editor Toolbar Buttons on page 37.
- New Editor options Allow search to wrap and Skip blank lines when tracing. See New Editor Options on page 37.
- New Tracer extension to allow the Editor to be called when the cursor is on any whitespace.
- New Editor option Remember previous window position (Classic Mode only)
- New Tracer option Limit tracer display to function in script.
- Facility to customise the window captions for the IDE. See Window Captions on page 42.
- New function Set Workspace Save Options determines whether or not the system will reset Trace, Stop and Monitor settings whenever a workspace is saved. See Set Workspace Save Options on page 120.
- Value tips can now be used to investigate the syntax of external functions.

## .NET Interface

- Under a licensing agreement with Syncfusion, Dyalog includes the Syncfusion library of WPF controls. These may be used by Dyalog APL users to develop applications, and may be distributed with Dyalog APL run-time applications.The Syncfusion libraries comprise a set of .NET assemblies which are supplied in the Syncfusion/4.5 sub-directory of the main Dyalog APL installation directory (for example: c: $\mid$ Program Files $\backslash$ Dyalog $\backslash$ Dyalog APL-64 14.0 Unicode\Syncfusion\4.5.. See Syncfusion Libraries on page 169.
- Version 14.0 includes support for Data Binding. See Example 1 on page 147.
- The .NET interface includes a new DLL. The dyalogdata4.5.dll provides advanced support for Data Binding and Syncfusion. In particular it provides the INotifyCollectionChanged interface which is required to support data binding of collections and lists. This DLL requires .NET Version 4.5 and is not used unless .NET 4.5 is enabled.
- It is now possible to specify overloads and casts for calling .NET functions.

## APL Applications as Windows Services

Features to allow the implementation of APL applications as Windows Services are now integrated into the Dyalog system.

## System Requirements <br> Microsoft Windows

Dyalog APL Version 14.0 supports versions of Windows from Microsoft Windows XP up to and including Microsoft Windows 8.1 and Microsoft Windows Server 2012. Dyalog APL Version 14.0 will not run on earlier versions.

## Microsoft .Net Interface

Dyalog APL Version 14.0 .NET Interface requires Version 2.x or greater of the Microsoft .NET Framework. It does not operate with .NET Version 1.0.

For Windows Presentation Foundation (WPF) and basic Data Binding, Version 14.0 requires .NET Version 4.0.

For full Data Binding support (including support for the INotifyCollectionChanged interface ${ }^{1}$ ), and Syncfusion, Version 14.0 requires .NET Version 4.5.

## AIX and Linux

For AIX, Version 14.0 requires AIX 6.1 or higher, and a POWER5 chip or higher.
Version 14.0 is built on RedHat 5, and runs on all recent distributions, including Ubuntu 12.04 and openSUSE 12.3. Contact Dyalog for information about other platforms.

[^0]
## Interoperability

## Introduction

Workspaces and component files are stored on disk in a binary format (illegible to text editors). This format differs between machine architectures and among versions of Dyalog. For example a file component written by a PC may well have an internal format that is different from one written by a UNIX machine. Similarly, a workspace saved from Dyalog Version 14.0 will differ internally from one saved by a previous version of Dyalog APL.

It is convenient for versions of Dyalog APL running on different platforms to be able to interoperate by sharing workspaces and component files. From Version 11.0, component files and workspaces can generally be shared between Dyalog interpreters running on different platforms. However, this is not always possible, for example:

- Component files created by Version 10.1 can often not be shared across platforms, even when used by later versions.
- Small-span (32-bit) component files become read-only when opened on a different architecture from that on which they were created.

Note however that the system function DF COPY can be used to make a logically identical copy of an old file, which is fully inter-operable.

The following sections describe other limitations in inter-operability:

## Code

Code which is saved in workspaces, or embedded within [ORs stored in component files, can generally only be read by the version which saved them and later versions of the interpreter. In the case of workspaces, a load (or copy) into an older version would fail with the message:

```
this WS requires a later version of the interpreter.
```

Every time a $\operatorname{DOR}$ object is read by a Version later than that which created it, time may be spent in converting the internal representation into the latest form. Dyalog recommends that DOR should not be used as a mechanism for sharing code or objects between different versions of APL

## "Ordinary" Arrays

With the exception of the Unicode restrictions described in the following paragraphs, Dyalog APL provides inter-operability for arrays which only contain (nested) character and numeric data. Such arrays can be stored in component files - or transmitted using TCPSocket objects and Conga connections, and shared between all versions and across all platforms.

As mentioned in the introduction, full cross-platform interoperability of component files is only available for large-span component files (see the following section), and for small-span component files created by Version 11.0 or later.

## 32 vs. 64-bit Component Files

Large-span (64-bit-addressing) component files are inaccessible to versions of the interpreter that pre-dated their introduction (versions earlier than 10.1).

From version 14.0 onwards it is no longer possible to create small-span (32-bit) files; Version 14.0 is still able to read and write to small span files. Setting the second item of the right argument of पF CREATE will generate a DOMAIN ERROR.

Note that small-span (32-bit-addressing) component files cannot contain Unicode data. Unicode editions of Dyalog APL can only write character data which would be readable by a Classic edition (consisting of elements of $\square \mathrm{AV}$ ).

## External Variables

External variables are implemented as small-span (32-bit-addressing) component files, and subject to the same restrictions as these files. External variables are unlikely to be developed further; Dyalog recommends that applications which use them should switch to using mapped files or traditional component files. Please contact Dyalog if you need further advice on this topic.

## 32 vs. 64-bit Interpreters

From Dyalog APL Version 11.0 onwards, there are two separate versions of programs for 32-bit and 64-bit machine architectures (the 32-bit versions will also run on 64 bit machines running 64 -bit operating systems). There is complete inter-operability between 32 - and 64-bit interpreters, except that 32-bit interpreters are unable to work with arrays or workspaces greater than 2 GB in size.

## Unicode vs. Classic Editions

From Version 12.0 onwards, a Unicode edition is available, which is able to work with the entire Unicode character set. Classic editions (a term which includes versions prior to 12.0 ) are limited to the 256 characters defined in the atomic vector, पAV).

Component files have a Unicode property. When this is enabled, all characters will be written as Unicode data to the file. The Unicode property is always off for smallspan (32-bit addressing) files, which may not contain Unicode data. For large-span (64-bit addressing) component files, the Unicode property is set on by Unicode Editions and off by Classic Editions, by default. The Unicode property can subsequently be toggled on and off using DF PROPS.

When a Unicode edition writes to a component file which may not contain Unicode data, character data is mapped using $\square A V U$, and can therefore be read without problems by Classic editions.

A TRANSLATION ERROR will occur if a Unicode edition writes to a non-Unicode component (that is either a 32-bit file, or a 64-bit file when the Unicode property is currently off) if the data being written contains characters which are not in DAVU.

Likewise, a Classic edition (Version 12.0 or later) will issue a TRANSLATION ERROR if it attempts to read a component containing Unicode data not in DAVU from a component file. Version 11.0 cannot read components containing Unicode data and issues a NONCE ERROR.

A TRANSLATION ERROR will also be issued when a Classic edition ) LOADs or ) COPYs a workspace containing Unicode data which cannot be mapped to $\square A V$ using the DAVU in the recipient workspace.

TCPSocket objects have an APL property which corresponds to the Unicode property of a file, if this is set to Cl assic (the default) the data in the socket will be restricted to $\bar{A} V$, if Unicode it will contain Unicode character data. As a result, TRANSLATION ERRORs can occur on transmission or reception in the same way as when updating or reading a file component.

## AVU changes

The implementation of the function Right in Version 13.0 led to the discovery that
 Tack, DUCS 8866). This error has been corrected in the default पAVU and in workspace AVU. dws. If you are operating in a mixed Unicode/Classic environment, this error will have caused earlier Classic editions to map $\overline{\text { AV }}[59+\square$ IO $]$ to the wrong Unicode character ( $\mathfrak{x}$ ). This may cause TRANSLATION ERRORs when a Version 13.0 Classic system attempts to read the data, as it will not be able to represent $x$ in the Atomic Vector.

## DECFs and Complex numbers

Version 13.0 introduced two new data types; DECFs and Complex numbers. Attempts to read components of these types in earlier interpreters will result in a DOMAIN ERROR.

## Very large array components

The maximum size (in bytes) of a component written by Version 12.1 and prior is 2GB. This is the size of the component as held on disk which may be different than the size reported by ZSIZE. In Version 13.0 the maximum size of a component written by a 64 -bit interpreter is 4 GB . From Version 13.2 onwards, the limit on the size of arrays or components is so large that for most practical purposes, there is effectively no limit.

An attempt to read a component greater than 2GB in 32-bit interpreters will result in a WS FULL. An attempt to read such a component in 64-bit Versions 12.0 and 12.1 patched after 1st April 2011 will result in a NONCE ERROR; earlier patches generate aFILE COMPONENT DAMAGED error.

## File Journaling

Version 12.0 introduced File Journaling (level 1), and 12.1 added journaling levels 2 and 3 and checksumming. Versions earlier than 12.0 cannot tie files which have any form of journaling or checksumming enabled. Version 12.0 cannot tie files with journaling levels greater than 1 , or checksumming enabled. Attempting to tie such files will result in a FILE NAME ERROR. Files can be shared with earlier versions by using DFPROPS to amend the journaling and checksumming levels.

## File Component Compression

Version 14.0 introduced File Component Compression; earlier versions will be able to perform all file operation on such files with the exception of being able to
DFREAD any compressed component. In particular, it is possible for any earlier version to DFREPLACE a compressed component with a non-compressed one.

Attempting to read a compressed component using earlier versions of Dyalog APL will generate an error:

- All 13.2 and 13.1.14842 and later: DOMAIN ERROR: Array is from a later version of APL
- 13.1 before revision 14842:

FILE COMPONENT DAMAGED: Incoming array is invalid

- 13.0 and 12.1 after revision 11154 :

DOMAIN ERROR

- 13.0 and 12.1 before revision 11154:

FILE COMPONENT DAMAGED

## TCPSockets

TCPSockets used to communicate between differing versions of Dyalog APL are subject to similar limitations to those described above for component files. In particular TCPSockets with 'Style' 'APL' will only be able to pass arrays that are supported by both versions.

## Auxiliary Processors

A Dyalog APL process is restricted to starting an AP of exactly the same architecture. In other words, the AP must share the same word-width and byte-ordering as its interpreter process.

## Session Files

Session (.dse) files may only be used on the platform on which they were created and saved.

## Announcements

## Withdrawal of Support for Version 12.1 and 13.0

The supported Versions of Dyalog APL are now Version 14.0, Version 13.2 and Version 13.1. Versions 13.0, 12.1 and earlier are no longer supported.

## Migration Level ( $\square$ ML)

In Version 14.0, the default value of CML in a CLEAR WS has been changed from 0 to 1 . This means that monadic $\epsilon$ is interpreted as Enlist and not as Type. Note that the value of $\square M L$ in saved workspaces is unaffected by this change. Note too that this default value may be overridden using the default_ml parameter. See User Guide for details.

## Deprecation of small-span component files

Since Version 10.1, Dyalog APL has supported large-span (64-bit) component files, and since Version 12.0 DF CREATE has created these by default.

From Version 14.0 onwards it is not possible to create small-span component files, although you may continue to read and write components on existing small-span component files.

Dyalog recommends that you convert any existing small-span component files to large-span files using DFCOPY. DF COPY will create a large-span copy even if the file being copied is small-span. You may use the user command ]Files.tolarge to locate existing small-span files and convert them to the large-span architecture.

Dyalog APL now ignores the -F32 argument, as well as the APL_FCREATE_ PROPS_S environment variable.

## Auxiliary Processors

In Version 14.0, the Dyalog-supplied Auxiliary Processor $q f s c k$ has been removed from the product. Anybody still using fsck is advised to switch to DFCHK instead.

The auxiliary processors strand and xutils are still included with Version 14.0, but the intention remains to remove them as soon as possible.

The interfaces for user-written Auxiliary Processors will continue to be supported.

## Random Number Generator

In Versions 13.1 and 13.2 the default random number generator in a CLEAR WS was 0 (Lehmer linear congruential).

In Version 14.0 the default is 1 (Mersenne Twister).
Note: the change to the default will only impact applications if they are rebuilt from a clear workspace; saved workspaces will be unaffected.

## Recommendation concerning Component Files

Dyalog strongly recommends that Component files should be protected by Journalling and have Checksum enabled. See File Properties on page 76.

## FontObj Property

The FontObj property should no longer be used directly to specify the properties of a font. It should only be used to specify the Font object to be used, which in turn specifies the characteristics of a font.

## Carriage Return Change (UNIX only)

Previously, the expression [UCS $\operatorname{ZAV[3+\square IO]~returned~} 133$ (NEL) in Unicode UNIX versions. In all other versions it returned 13 (CR).

From Version 14.0, all versions of Dyalog APL return 13.
Note: the change to the default will only impact applications if they are rebuilt from a clear workspace; saved workspaces will be unaffected.

## .NET Support

Support for Microsoft .Net Version 2 will cease in Dyalog APL Version 15.0.

## New Method

Currently Dyalog APL adds a method named New to all .Net objects which do not have such a member. This allows the APL programmer to create an instance of an object (such as in this example a DateTime object) by executing the statements:

$$
\begin{aligned}
& \text { ZUSING*'System' } \\
& \text { dt+DateTime.New } 1949430
\end{aligned}
$$

Dyalog intends to remove this feature from future versions of Dyalog APL. This mechanism was made redundant by the introduction of DNEW, and the following syntax should be adopted:

$$
\text { dt- पNEW DateTime (1949 } 4 \text { 30) }
$$

## UpperCase Property

Dyalog intends to remove the Uppercase Property as a property of Root in future versions of Dyalog APL. Since Version 12.0 its value has had no effect.

## Dyalog-added .New method

In Version 14.0 and prior the interpreter would add a .New method to any .NET object which did not have one of its own. This was introduced when NEW was not part of the language. From Version 14.1 onwards the interperter will no longer add a .New method.

## DWSIN/DWSOUT

The workspaces DWSIN and DWSOUT have been removed from version 14.0; ]in and ]out should be used instead. More details can be found in the Dyalog APL Workspace Transfer Guide.

## DFNS

The dfns.dws workspace is now supplied in the ws sub-directory and not in the samples sub-directory as before.

## TCPIP

The sample workspace samples $\backslash$ tcpip. dws is no longer supplied and is no longer supported.

## aplserve

The sample web server which was previously provided in the aplserve sub-directory is no longer supplied nor supported.

## Performance Improvements

Dyalog APL Version 14.0 provides a large number of performance improvements, including the following:

## New Idioms

The following new idioms are recognised:

| Expression | Description |
| :--- | :--- |
| LO.5+NA | Round to nearest integer |

## Inverted Table Index-of

An inverted table is a data structure that is commonly used in APL applications to handle relational data. The (8I) derived function provides a fast and efficient means to perform a table look-up of one inverted table in another. See Inverted Table Index Of on page 103 .

## Component File Operations

The performance of reading and writing APL components has been improved by better use of buffering and other changes.

## Boolean Operations which are faster in 14.0 than in 13.2

- All structural functions such as $\uparrow \downarrow \rho$ [;] [ , $\phi \theta$ on Boolean arrays
- BV/ヶpBV
- BV/ぇNS
- $B V_{\imath 1} 1$ and $B V_{\imath 0}$
- $B V 1 / B V 2$ and $B V 1+B V 2$ and $B V /[k] B V 2$
-     + \[k]BV
- BA1=BA2

## Other operations which are faster in 14.0 than in 13.2

- Simple indexing including bracket indexing, bracket indexed assignment, and squad indexing
- $\uparrow$ [DIO-0.5] PV
- NV1[NV2]++1 when NV2 is not in strictly ascending numerical order
- associative arithmetic scans $+\backslash[k] N A$ and $\times \backslash[k] N A$ and $L \backslash[k] N A$ and $\Gamma \backslash$ [k]NA
- LNA and「NA when DCT is 0

Where:

| BV | Boolean vector |
| :--- | :--- |
| BA | Boolean array |
| PV | nested vector |
| NV | numeric vector |
| NA | numeric array |

## Bug Fixes

A number of bug fixes implemented in Version 14.0 may change the way that exist－ ing code operates and are therefore documented in this section．

## Matrix Inverse with scalar argument

If the argument to monadic 因 is scalar，the result should be scalar．In previous ver－ sions the result was a 1 －element vector．This correction may change the way that existing code works，especially as the bug has been there since the earliest imple－ mentation of Dyalog．

固2
0.5

دp圆2 $\mu$ Version 13.1 and earlier
1
＞$\rho$ 目2 $ค$ Version 14.0
0

## Change Data Type

Previously，the Unicode Edition of Dyalog APL accepted a left argument of 82 （8－ bits character）treating it as if it were 80．It now signals an error．

## Version 13.2

82 TDR 65
A
Version 14.0
82 TDR 65
DOMAIN ERROR：Invalid conversion code 82 TDR 65
$\wedge$

## Threads and Error Trapping

If a function sets a global（catch all）trap，then spawns a thread with the intention that the trap should be in effect for the new thread，and subsequently introduces a new local ：Trap or dfn error guard，it was possible that an error in the spawned thread would be caught by the second trap and not the first．This has now been resolved．

## .Net Object Property Assignment

In version 14.0 the interpreter will no longer accept a one element vector as the value of a .Net object Property that is expected to be a single numeric value; only a simple scalar value will be accepted.

In 13.2 and prior, the interpreter would (incorrectly) pass a scalar rather than a single element vector as the value when assigning to a .Net Property that expected a vector, which lead to unexpected errors. In 14.0 the interpreter (correctly) insists that a vector Property is passed a vector and a scalar Property is passed a scalar value.

## Example

```
    \squareusing*''
    s&\squarenew System.IO.MemoryStream
    s.Capacity
0
        s.Capacity 
        s.Capacity\leftarrow,100
DOMAIN ERROR
    s.Capacity\leftarrow,100
    ^
```

This last assignment will succeed in Version 13.2 and prior.

## Chapter 2:

## New Language Features

## Function Trains

A Train is a sequence of 2 or 3 items in an expression which bind together to form a function. Each item in a train may be an array or a function but the right-most item must be a function.

Note that the right-most item of a function train (which is by definition a function) must be isolated from anything to its right, otherwise it will be bound to that rather than to the items to its left. This is done using parentheses.

For example, the following expression comprises a function train,$- \div$ that is separated from its argument 2 by parentheses:

```
    (-,\mp@code{) 2}
-2 0.5
```

and means:

1. Calculate the reciprocal of 2
2. Calculate the negation of 2
3. Catenate these 2 results together

Whereas, without the parentheses to identify the function train, the expression means (as it did before):

1. Calculate the reciprocal of 2
2. Ravel the result of step 1
3. Negate the result of step 2
$-, \div 2$
-0. 5
For further information, see Function Trains on page 72.

## Key Operator

In the expression $X f$ 目 $Y$ the Key operator目 ${ }^{1}$ applies the function $f$ to the major cells of array Y grouped by a set of keys which are specified by the major cells of array X ． For further details，see Key on page 65.

Consider a simple example where FRUIT and QTY are both vectors that represent sales transactions of fruit．Note that the major cells of a vector are its items．

```
    FRUIT<'oranges' 'pears' 'apples' 'pears' 'oranges'
    QTY<12 4 5 10 7
    FRUIT,[1.5]QTY
oranges 12
pears 4
apples 5
pears 10
oranges 7
    FRUIT {\alpha,+/\omega} 目 QTY
oranges 19
pears 14
apples 5
```

In the expression FRUIT $\{\alpha,+/ \omega\}$ 目QTY，目 first calculates the set of unique elements of FRUIT．It then groups together the elements of QTY which relate to the same unique element of FRUIT．In this case，QTY［ 1 5 $]$ ］relates to＇oranges＇，QTY［2 4］relates to＇pears＇and QTY［3］relates to＇apples＇．

It then pairs each unique FRUIT with each corresponding subset of QTY and applies the function $\{\alpha,+/ \omega\}$ between each pair，with each unique FRUIT as its left argu－ ment and each subset of QTY as its right argument．Specifically，it applies function $\{\alpha,+/ \omega\}$ three times with arguments as follows：

```
(c'oranges') {\alpha,+/\omega} (12 7)
(c'pears') {\alpha,+/\omega} (4 10)
(c'apples') {\alpha,+/\omega} (,5)
```

[^1]
## Index Of

Dyadic $\imath$ has been extended to matrices and higher-rank arrays, so that sub-arrays specified by the right argument may be located in the left argument.

Specifically, this applies to major cells of the left argument x , where a major cell is a sub-array on the leading dimension of $x$ with shape $1 \downarrow \rho x$. The major cells of a matrix are its rows.

Until now, the idiom $\{(\downarrow \alpha) \imath \downarrow \omega\}$ was the best way to look up rows of one matrix in another (often called the matiota idiom). This extension to dyadic $\imath$ provides a more concise solution that is equally as fast, so renders the idiom redundant.
(3 4 $\rho \imath 6$ ) $\{(\downarrow \alpha) \imath \downarrow \omega\} 104 \rho \imath 6$
1231231231
(3 4pr6) 乙 $104 \rho \imath 6$
1231231231
For further information, see Index Of on page 57

## Mix

Mix ( $\uparrow \omega \operatorname{if} \square \mathrm{ml}<2$; $\supset \omega$ if $\square \mathrm{ml} \geq 2$ ) has been extended.
Previously, if any items in the argument (with the exception of scalars) had different rank, the function would signal a RANK ERROR. Now, it automatically extends the rank of non-scalar items in the argument to that of the largest rank by padding their shape with leading ones.

## Version 13.2

```
        ^(2 2)(2 3p3)
```

RANK ERROR
$\uparrow\left(\begin{array}{l}2\end{array}\right)\left(\begin{array}{ll}2 & 3 \rho 3\end{array}\right)$
$\wedge$

## Version 14.0

$\uparrow\left(\begin{array}{l}2\end{array}\right)(23 \rho 3)$
220
000
333
33
In this case, the rank of the first item, the vector (2 2 ) is extended to that of the second (a matrix) by prefixing its shape with 1 ; so it becomes ( $\begin{array}{ll}1 & 2 \rho 2\end{array} 2$ ). The result then obtains from $\uparrow\left(\begin{array}{ll}1 & 2 \rho 2\end{array}\right.$ ) (2 $\left.3 \rho 3\right)$.

Note that the extended mix is also exploited in the implementation of the new Rank and Key operators.

## Mix With Axis

The APL2-compatible version of Mix ( $\supset \omega$ when $\square \mathrm{ml} \geq 2$ ) has been extended.
Previously, in the expression $\supset[K] Y$, the axis specifier $K$ was a scalar integer which set the position of the axes of the items of $Y$ in the shape of the result.

## Example

$$
\vdash Y \leftarrow 5 \quad 4 \rho(\imath 20) \times c 3 \quad 2 \rho 1
$$

| 1 | 1 | 2 | 2 | 3 | 3 | 4 | 4 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 1 | 2 | 2 | 3 | 3 | 4 | 4 |
| 1 | 1 | 2 | 2 | 3 | 3 | 4 | 4 |
| 5 | 5 | 6 | 6 | 7 | 7 | 8 | 8 |
| 5 | 5 | 6 | 6 | 7 | 7 | 8 | 8 |
| 5 | 5 | 6 | 6 | 7 | 7 | 8 | 8 |
| 9 | 9 | 10 | 10 | 11 | 11 | 12 | 12 |
| 9 | 9 | 10 | 10 | 11 | 11 | 12 | 12 |
| 9 | 9 | 10 | 10 | 11 | 11 | 12 | 12 |
| 13 | 13 | 14 | 14 | 15 | 15 | 16 | 16 |
| 13 | 13 | 14 | 14 | 15 | 15 | 16 | 16 |
| 13 | 13 | 14 | 14 | 15 | 15 | 16 | 16 |
| 17 | 17 | 18 | 18 | 19 | 19 | 20 | 20 |
| 17 | 17 | 18 | 18 | 19 | 19 | 20 | 20 |
| 17 | 17 | 18 | 18 | 19 | 19 | 20 | 20 |

Notice where the ( 32 ) appears in the following results:

```
3 2 5 4
    \rho[2]Y
5 3 2 4
    ~[3]Y
5432
```

In Version 14.0, a vector $K$ allows the axes of the items of $Y$ to be distributed in the shape of the result, instead of being contiguous. Notice where the 3 and the 2 appear in the following results:

```
    \rho[[1 3]Y
3 5 2 4
    \rho[1 4]Y
3 5 4 2
    \rhoد[4 2]Y
5 24 3
```

## Rationalisation of Monadic Operators

Like primitive functions, monadic operators can be:

- named
- enclosed within parentheses
- displayed in the session

## Examples

```
    \square
    shape}
    shape each (1 2) (3 4 5)
    2 3
    slash*/
    +slash \imath10
5 5
    swap*\ddot{~}
    3 -swap 4
1
```

Note that dyadic operators are not promoted to first-class and so may not in general be named or displayed. A dyadic operator may however be bound with its right operand to form a monadic operator, i.e. a first class citizen. See Right Operand Currying on page 25 .

## Right Operand Currying

A dyadic operator may be bound or curried with its right operand to form a monadic operator:

## Examples

```
    | & inv * **-1
    A produces monadic inverse operator
* -1
    +\inv 1 2 3 A scan-inverse
111
    lim * \ddot{x }\quad\rho power-limit
    1 +o\divlim 1 ค Phi
1.61803
```

## Note:

The following restrictions continue to apply to Version 14.0 but may be relaxed in a later release:

- Dyadic operators are not promoted to first-class and so may not in general be named or displayed
- Left operand currying is not supported

## Examples

```
    \circ & Dyadic operator not first-class
SYNTAX ERROR
    c\ddot{*}\quad A No left-operand currying
SYNTAX ERROR
```

## Random Link Extension

Certain applications require a non-repeatable series of pseudo-random numbers, and several programming techniques exist to meet this requirement (such as generating a seed from the system clock) which are not always satisfactory. In Version 14.0, you may have the system itself generate a random seed by assigning the value 0 to $\square R L$.

If $\square R L$ is assigned the value $0, \square R L$ is initialised with a random seed generated by the operating system. This provides the means to initiate a non-repeatable series of pseudo-random numbers when using $R N G 0$ or $R N G 1$.

## Summary

In the following tables, $A$ is an integer that specifies the type of operation to be performed.

I-Beam functionality removed from Version 14.0.

| A | Derived Function |
| :--- | :--- |
| 685 | UNIX only: core to aplcore |

I-Beam functionality extended in Version 14.0.

| A | Derived Function |
| :--- | :--- |
| 1111 | Number of Threads/Virtual Processors |

I-Beam functionality added to Version 14.0.

| $\mathbf{A}$ | Derived Function |
| :--- | :--- |
| 8 | Inverted Table Index-of |
| 181 | Unsqueezed Type |
| 219 | Compress/Decompress Vector of Short Integers |
| 220 | Serialise/Deserialise Array |
| 1159 | Update Function Time and User Stamp |
| 2002 | Specify Workspace Available |

| A | Derived Function |
| :--- | :--- |
| 2015 | Data Binding |
| 2022 | Flush Session Caption |
| 2023 | Close all Windows |
| 2400 | Set Workspace Save Options |
| 2401 | Expose Root Properties |

## New Symbols in Classic Edition

The symbols for the 2 new operators introduced in Version 14．0，namely 目（Key）and $\ddot{\circ}$（Rank），and the previously introduced symbol 1 （Variant）are not provided in Clas－ sic Edition．

If you create a function in a non－scripted namespace（including the root namespace） containing these symbols in a Unicode Edition，）SAVE the workspace and then ） LOAD the workspace using Classic Edition，the symbols will be replaced by strings in the form DUnnnn as shown in the table below．

These strings may be entered and edited in the Classic Edition editor and will be re－ fixed as the corresponding operators．In Unicode Edition，only the correct symbols may be used；the substitution strings will not be understood．

| Symbol | Substitution String（Classic Edition only） |
| :--- | :--- |
| 日 | QU2360 |
| 目 | QU2338 |
| $\because \because$ | QU2364 |

Replacement of these symbols with their substitution strings and vice versa will only occur when they appear in code in the body of functions which appear in non－scrip－ ted namespaces．Replacement will not happen when they appear in：
－comments in functions
－character constants in functions
－any scripted object（this includes functions defined in scripted objects）
－variables
When attempting to ）LOAD or ）COPY a workspace that does not meet the above cri－ teria into a Classic Edition，a TRANSLATION ERROR will be signalled．In 14.0 the error message includes the character which has caused the operation to fail；bear in mind that this is the first occurrence of the first character which will generate a TRANSLATION ERROR；there may be more instances of this character，and there may be other characters too．

## Chapter 3:

## Component File Improvements

## File Read

DFREAD has been enhanced to allow you to read several components at one time, without the use of the Each (*) operator. It differs from the equivalent operation using Each in that it is faster and is an atomic operation that does not permit an intervening file operation by a different user.

To effect this enhancement, the second element of the argument may now be a vector of component numbers, rather than just a single component number as before.

```
Example
    'temp'DFCREATE 1
    (\imath10)DFAPPEND"1
    DFSIZE 1
1112240 1.844674407E19
    DFREAD 1 (r10)
12345678910
```

## Compressed Components

In Version 14.0, you may now create compressed components. Components are compressed using the LZ4 compressor which delivers a medium level of compression, but is considered to be very fast compared to other algorithms.

Compression is intended to deliver a performance gain reading and writing large components on fast computers with slow (e.g. network) file access. Conversely, on a slow computer with fast file access compression may actually reduce read/write performance. For this reason it is optional at the component level.

This feature is implemented by a new file property ' $Z$ ' which may be set using DFPROPS, or by a function derived fromDFCREATE with the Variant operator B. $^{\text {. }}$

The default for the ' $Z$ ' property is 0 which means no compression; 1 means compression. When written, components are compressed or not according to the current value of the ' $Z$ ' property. Changing this property does not change any components already in the file.

A component file may therefore contain a mixture of normal and compressed components. Note that only the data in file components are compressed, the file access matrix and other header information is not compressed.

When read, compressed components are decompressed regardless of the value of the 'Z' property.

Compression is not supported for files in which both Journalling and Checksum are disabled.

Attempting to read compressed components using earlier versions of Dyalog APL will generate an error:

- All 13.2 and 13.1.14842 and later: DOMAIN ERROR: Array is from a later version of APL
- 13.1 before revision 14842 : FILE COMPONENT DAMAGED: Incoming array is invalid
- 13.0 and 12.1 after revision 11154 : DOMAIN ERROR
- 13.0 and 12.1 before revision 11154:
file component damaged

## File Create and Variant

Previously，if you wanted to create a component file with non－default properties，it was necessary to execute two steps，namely：

1．Create the file using DFCREATE
2．Set the File Properties using DFPROPS
Without changing the syntax of $\square F C R E A T E$ it is now possible to achieve this in one step because in Version 14．0 DF CREATE supports the variant operator $\mathrm{B}^{\mathrm{O}}$ and the fol－ lowing options：
－＇J＇－journaling level；a numeric value
－＇C＇－checksumming level； 0 or 1
－＇Z＇－compression； 0 or 1
The principal option is a combination as follows：
－0－sets（＇J＇0）（＇C＇0）
－1－sets（＇J＇1）（＇C＇1）
－ 2 －sets（＇J＇2）（＇C＇1）
－3－sets（＇J＇3）（＇C＇1）

## For example，

＇newfile＇（口fCREATE目3）0
1
＇SEUJCZ＇DFPROPS 1
6401310
Alternatively：
JFCREATE－DFCREATE 日 3
will name a variant of DFCREATE which will create component file with level 3 journaling，and checksum enabled．Then：

```
'newfile'JFCREATE O
```

## File Check and Variant

DFCHK, which was implemented before the Variant operator was introduced, has been changed to support the use of Variant to set options. This has been done for consistency. However, the existing method for setting the options via its left argument will continue to be supported. There are 3 options:

- Task
- Repair
- Force

Rebuild causes the file indices to be discarded and rebuilt. Repair only takes place on files which have been checked and found to be damaged. It involves a rebuild, but that only takes place if it is needed. Note that Repair and Force only apply if Task is 'Scan'.

Task

| Scan | causes the file to be checked and optionally repaired (see <br> 'Repair' below) |
| :--- | :--- |
| Rebuild | causes the file to be unconditionally rebuilt |

## Repair (principle option)

| 0 | do not repair |
| :--- | :--- |
| 1 | causes the file to be repaired if damage is found |

## Force

| 0 | do not validate the file if it appears to have been properly <br> closed |
| :--- | :--- |
| 1 | validate the file even if it appears to have been properly closed |

Default values are highlighted thus in the above tables.

## Examples

To check a file and attempt to fix it if damage is found:
(DFCHK 日 1)'suspect.dcf'
To forcibly check a file and attempt to fix it if damage is found:

Note that if options are specified using both the Variant operator and a left argument, the left argument overrides Variant. For example:

names a variant of DFCHK (identical, in this example, to the default) which can still be overridden by a left argument.

```
'rebuild' MYFCHK 'myfile'
```

## Chapter 4: Miscellaneous

## IDE Enhancements

## New User Commands

Two new User Commands, ]boxing and Jrows provide alternate forms of displaying output in the Session.

## Jboxing

The box ing user command has the following arguments:

- on
- off
and the following modifiers:
- -style= min|mid|max
- -trains = box|tree|parens
- -fns = on |off
- -chars = regular|chars

If boxing is on, arrays resulting from expressions entered in the Session are displayed with a series of boxes bordering each sub-array. The -style modifier controls the amount of information provided in each border. The -trains modifer controls how function trains (see Function Trains on page 19) are displayed. The - f ns modifier controls whether or not boxing is applied to output generated within a function. The - chars modifier selects the type of symbol used to draw the borders.

## Examples

```
    ]boxing
Is OFF
    \imathて3
```

```
    1 2 1 1 2 2 1 2 3
    ]boxing on
Was OFF
    \imathて3
```

| 1 | 1 | 1 | 1 | 1 | 2 | 1 | 1 | 3 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 2 | 1 | 1 | 2 | 2 | 1 | 2 | 3 |

## Jrows

The Jrows user command controls how rows in multi-row output to the Session are displayed. In place of the standard behaviour controlled by the auto-pw parameter or [PW, Jrows allows multi-row output to be truncated or wrapped to fit the Session window, or folded and cut.

## Aligning Comments

There is a new Editor command, AC, which is used to align comments in a function in an edit window.

When you press the $<\mathrm{AC}>$ key, or select Align Comments in the Editor's context menu, the alignment of the comments in every line in the function will be changed so that the left-most comment (Lamp) symbol is in the same column as the cursor, except that:

- Comment symbols that lie between the first column and the first tab stop will remain in or be moved to the first column. For information on setting tab stops, see Installation \& Configuration Guide: Configuration Dialog (Edit/Trace Tab).
- Comment symbols will not move further left than the end of the statement.

When a comment is re-aligned, text to the right of the left-most comment symbol (including spaces and other comment symbols) will remain fixed in relation to that symbol.

Note that there is no keystroke associated with this command by default; the user must define one. See Installation \& Configuration Guide: Configuration Dialog (Keyboard Shortcuts Tab).

## New Editor Toolbar Buttons

There are two new buttons on the Editor Toolbar whose functions are as follows:

国 Specifies whether or not the search examines collapsed Search hidden text blocks
aA
Match case

Specifies whether or not the search is case-sensitive.
This setting is shared with the case-sensitivity setting in the Find/Replace Tool

## New Editor Options

## Remember previous Window position (ClassicModeSavePosition parameter)

This parameter specifies whether or not the current size and location of the first of the editor and tracer windows are remembered for next time. It applies only when Classic Mode is enabled.

The size and location of the windows are saved in the registry in the subfolder WindowRects/EditWindow and TraceWindow.

## Allow search to wrap <br> (WrapSearch parameter)

This parameter specifies whether or not Search/Replace in the Editor stops at the bottom or top of the text (depending upon the direction of the search), or continues the search from the start or end as appropriate.

## New Tracer Options

There are two new options for the Tracer namely Skip blank lines when tracing and Limit tracer display to function in script, which are enabled or disabled using the option buttons in the Configuration Dialog: Trace/Edit Tab as shown below.

## Skipping comments and blank lines(SkipBlankLines parameter)

This parameter causes the Tracer to automatically skip lines that contain no executable statement (i.e. blank lines and comment lines), with the exception of the first line in the function, and in the case of a traditional function (not a dfn), the last line if it is a comment.

## Limit tracer display to current function in script (AddClassHeaders parameter)

This parameter specifies what the Tracer displays when tracing the execution of a function in a script. If set to 1 , the Tracer displays just the first line of the script and the function in question. If set to 0 , the entire script is shown in the Tracer window.

## Editor, Tracer and scripted objects

## Editor, Tracer and objects fixed in scripted objects

A scripted object can be created either by using the Editor or by calling DF IX.
The source of a scripted object can be altered only using the Editor, or by refixing using DF IX. Dynamic changes to variables, fields and properties, and calling DFX to generate functions do not alter the source of a scripted object. This behaviour has not changed since the introduction of scripted objects, and does not change in Version 14.0.

Prior to Version 14.0, DF Xing a function in a scripted object lead to apparent anomalies when tracing and editing such functions - the Tracer and Editor displayed the version of the function that was part of the source of the scripted object even though the $\quad \mathrm{F}$ Xed function was the version of the function that was being executed.

Now both the Tracer and the Editor display the DF Xed function; the statusfield will contain either "Unscripted function" or "Unscripted operator". In addition, if a function is in the source of a scripted object, the Editor and Tracer windows will display the whole script (possibly in a collapsed state) whereas a $\square$ F Xed function will display in a window on its own.

This behaviour is true when calling DF IXed in scripted object too.
A scripted object can be created either by using the Editor or by calling DFIX.

## Change to fixing scripted objects in the Editor

In Versions prior to 14.0 adding or removing a Stop on a line in a function in a scripted object would have lead to the function being refixed. This is no longer true.

## Value Tips for External Functions

Value Tips can also be used to investigate the syntax of external functions. If you hover over the name of an external function, the Value Tip displays its Function Signature.

For example, in the example below, the mouse is hovered over the external function dt . AddMonths and shows that it requires a single integer as its argument.

Should the external function provide more than one signature, they are all shown in the Value Tip as illustrated below. Here the function ToString has four different overloads.

## Window Captions

The captions of the various windows that comprise the Dyalog Integrated Development Environment (IDE) are user-configurable and defined by entries in the Windows registry in the Captions subkey of the main Dyalog key.

Note that this only applies when the windows are floating (un-docked). When a window is docked Dyalog displays a fixed non-configurable caption.

Note also that the Captions subkey is not created by the interpreter, the user must create the subkey and the values.

Each entry is a string value whose name identifies the window as follows:

| Window Name | Description |
| :--- | :--- |
| Session | The main Dyalog APL session window |
| Editor | The Editor window |
| MessageBox | The notification Message Box that is displayed in various <br> circumstances; for example, when an object cannot be fixed <br> by the Editor |
| Explorer | The Workspace Explorer tool |
| Rebuild Errors | The dialog box that is displayed if one or more objects <br> cannot be re-instantiated when a workspace is loaded |
| Status | The Status window |
| Refactor | The Refactor as Method/Field/Property window that is <br> displayed by the Editor |
| Event Viewer | The Event Viewer |
| FindReplace | The Find/Replace dialog box used by the Editor |
| ExitDialog | The Exit dialog box that is displayed when the user closes <br> the Session window |
| WSSearch | The Find Objects tool |

Each string value should contain a mixture of your own text and keywords which are enclosed in braces, e.g. \{TITLE\}. Keywords act like variables and are replaced at display time by corresponding values as described in the table below.

| Keyword | Value |
| :--- | :--- |
| \{TITLE \} | The window name shown in the first column of the previous <br> table |
| \{WSID \} | Workspace ID (QWSID) |
| \{NSID \} | Current Namespace |
| \{SNSID \} | Current Namespace (short version) |
| \{PRODUCT \} | The name of the Dyalog product, e.g. "Dyalog APL/W - 64" |
| \{VER_A \} | The main version number, e.g. "14" |
| \{VER_B \} | The secondary version number, e.g. "0" |
| \{VER_C \} | The tertiary version number (currently the internal revision <br> number) |
| \{PID\} | The process ID |
| \{CHARS \} | "Classic" or "Unicode" |
| \{BITS \} | "32" or "64" |
| $\{$ XLOC \} | The namespace currently being explored (Explorer only) |

For example, if the Registry contains .|Captions $\mid$ Session whose value is:
My APL (\{WSID\}) Version \{VER_A\}.\{VER_B\}[\{VER_C\}] - \{PID\}
then the caption displayed in a new Dyalog APL Session window might be:

```
My APL (CLEAR WS) Version 14.0[20105] - 4616
```

## Specifying Overloads and Casts for .Net

If a .NET function is overloaded in terms of the types of arguments it accepts, Dyalog APL chooses which overload to call depending upon the data types of the arguments passed to it. For example, if a .NET function foo () is declared to take a single argument either of type int or of type double APL would call the first version if you called it with an integer value and the second version if you called it with a noninteger value.

In some circumstances it may be desirable to override this mechanism and explicitly specify which overload to use.

A second requirement is to be able to specify to what .NET types APL should coerce arrays before calling a .NET function. For example, if a parameter to a .NET function is declared as type System. Object, it might be necessary to force the APL argument to be cast to a particular type of Object before the function is called.

Both these requirements are met by calling the function via the Variant operator B. $^{\text {. }}$ There are two options, OverloadTypes (the Principle Option) and CastToTypes. Each option takes an array of refs to .NET types, the same length as the number of parameters to the function.

## OverloadTypes Examples

To force APL to call the double version of function foo () regardless of the type of the argument val:
(foo 回('OverloadTypes'Double))val
or more simply:
(foo 回Double)val
Note that Double is a ref to the .NET type System. Double.

```
    ZUSING*'System'
    Double
(System.Double)
```

Taking this a stage further, suppose that $f \circ \circ()$ is defined with 5 overloads as follows:

```
foo()
foo(int i)
foo(double d)
foo(double d, int i)
foo(double[] d)
```

The following statements will call the niladic, double, (double, int) and double[] overloads respectively.

```
(foo 目(c0)) 0 ค niladic
(foo 目 Double) 1 & double
(foo 目(cDouble Int32))1 1 \rho double,int
(foo 目(Type.GetType c'System.Double[]'))c1 1 & double[]
```

Note that in the niladic case，an enclosed empty vector is used to represent a null ref－ erence to a ．NET type．

## CastToTypes Example

The ．NET function Array．SetValue（）sets the value of a specified element（or elements）of an array．The first argument，the new value，is declared as System．Object，but the value supplied must correspond to the type of the Array in question．APL has no means to know what this is and will therefore pass the value as is，i．e．in whatever internal format it happens to be at the time．For example：

```
ZUSING*'System'
    A create a Boolean array with 2 elements
    BA\leftarrowArray.CreateInstance Boolean 2
    BA.GetValue O & get the Oth element
0
    A attempt to set the Oth element to 1 (AKA true)
    BA.SetValue 1 0
EXCEPTION: Cannot widen from source type to target type
either because the source type is a not a primitive type
or the conversion cannot be accomplished.
test[5] BA.SetValue 1 0
    ^
```

The above expression failed because APL passed the first argument 1 ，unchanged from its current internal representation，as a 1－byte integer which does not fit into a Boolean element．

To rectify the situation，APL must be told to cast the argument to a Boolean as fol－ lows：

```
(BA.SetValue 目 ('CastToTypes'(Boolean Int32)))1 0
BA.GetValue O & get the Oth element
```

1

## Overloaded Constructors

If a class provides constructor overloads, a similar mechanism is used to specify which of the constructors is to be used when an instance of the class is created using ZNEW.

For example, if MyClass is a .NET class with an overloaded constructor, and one of its constructors is defined to take two parameters; a double and an int, the following statement would create an instance of the class by calling that specific constructor overload:
(DNEW : (cDouble Int32)) MyClass (1 1)

## APL Application as a Service Introduction

Dyalog APL provides a mechanism for users to register and manage an application workspace as a Windows service. The application workspace must implement an interface to handle messages from the Windows Service Control Manager (SCM) in addition to the code required to drive the application.

Windows Services run as background tasks controlled by the SCM. When the computer is started, Windows Services are run before a user logs on to the system and do not normally interact with the desktop. A Dyalog service is run under the auspices of Local System.

## Installing and Uninstalling a Dyalog Service

To install a Dyalog service it is necessary to run dyalog. exe from the command line with administrator privileges, specifying the application workspace and the following parameters, where service_name is a name of your choice.

- APL_ServiceInstall=service_name

The command must specify the full pathname to dyalog. exe and to the application workspace. A slightly modified version of this command line will be stored by the SCM and re-executed whenever the service is started.

Dyalog installs the service with a Startup Type of Automatic. This means that it will be started automatically whenever the computer is restarted. However, it is necessary to start it manually (using the SCM) the first time after it is installed.

The same command must be used to uninstall the service, but with:

- APL_ServiceUninstall=service_name

The following table summarises the parameters that can be specified by the user. Other parameters will appear on the command line in the SCM, but should not be specified by the user.

| Parameter | Description |
| :--- | :--- |
| APL_ServiceInstall | Causes Dyalog to register the named service, using <br> the current command line, but with APL__ <br> ServiceRun replacing APL_ServiceInstall in the <br> SCM. |
| APL_ServiceUninstall | Causes Dyalog to uninstall the named service. |

## The Application Workspace

The application workspace must be designed to handle and respond (in a timely manner) to notification messages from the SCM as well as to provide the application logic. SCM notifications include instructions to start, stop, pause and resume.

SCM notification messages generate a ServiceNotification event on the Root object. To handle these messages, it is necessary to attach a callback function to this event, and to invoke the Wait method or DDQ ' . ' to process them. This must be executed in thread 0 .

If the application is designed to be driven from events such as Timer or TCPSocket or user-defined events, it too may be implemented via callbacks in thread 0 under the control of the same Wait method or DDQ ' . ' . If the application uses Conga it is recommended that it runs in a separate thread.

The workspace samples $\backslash$ aplservice $\backslash a p l$ service. dws is included in the APL release. Its start-up function is as follows:

```
    \square\X\leftarrow'Start'
    \nabla Start;ServiceState;ServiceControl
[1] :If 'W'\not=3>#.\squareWG'APLVersion'
[2] D<'This workspace only works using Dyalog APL for
                Windows version 14.0 or later'
[3] :Return

[13] \rho Global variable defines current state of the service
[14] ServiceState\leftarrowSERVICE_RUNNING
[15] A Global variable defines last SCM notification to the
        service
[16] ServiceControl*0
[17] A Application code runs in a separate thread
[18] Main&O
[19] DDQ'.'
[20] DOFF
\nabla
```

## Handling ServiceNotification Events

To give the workspace (which may be busy) time to respond to SCM notifications, Dyalog responds immediately to confirm that the service has entered the appropriate pending state. For example, if the notification is SERVICE_CONTROL_STOP, Dyalog informs the SCM that the service state is SERVICE_STOP_PENDING. It is then up to the callback function to confirm that the state has reached SERVICE_ STOPPED.

The following sample function is provided in APLService.dws.

## ServiceHandler Callback Function

```
\nabla r<ServiceHandler(obj event action state);sink
[1]
    \rho Callback to handle notifications from the SCM
[2]
[3] A Note that the interpreter has already responded
[4] A automatically to the SCM with the corresponding
[5] & "_PENDING" message prior to this callback being reached
[6]
[7]
[8]
[9]
[10] r<0 A so returns a 0 result (the event has been handled,
[11] A no further action required)
[12]
[13] ค It stores the desired state in global ServiceState to
[14] A notify the application code which must take appropriate
[15] \rho action. In particular, it must respond to a "STOP or
[16] ค "SHUTDOWN" by terminating the APL session
[17]
[18] :Select ServiceControl*action

[20] ServiceState\leftarrowSERVICE_STOPPED
[21] state[4 5 6 7] % 0
[22]
[23]
:Case SERVICE_CONTROL_PAUSE
[24] ServiceState*SERVICE_PAUSED
[25]
[26]
[27]
[28]
[29]
[30]
[31]
[32]
[33] state[2]*ServiceState
[34] sink<2 [NQ'.' 'SetServiceState'state
\nabla
```

## The Application Code

The following function illustrates how the applcation code for the service might be structured. It is merely an illustration, but however it is done, it is important that the code handles the instructions to pause, continue and stop in an appropriate manner. In this example, the function Main creates a $\log$ file and writes to it when the state of the service changes.

```
\nabla Main arg;nid;log;LogFile
    ZNUNTIE INNUMS
[2] log\leftarrow{((क\squareTS),' ',\omega,DUCS 13 10)DNAPPEND \alpha}
[3] LogFile\leftarrow'c:\ProgramData\TEMP\APLServiceLog.txt'
[4] :Trap 22
[5] nid<LogFile DNCREATE O
[6] :Else
[7] :Trap 22
[8] nid\leftarrowLogFile DNTIE O
[9] O DNRESIZE nid

[11] }\quad\mp@subsup{\square}{<'Unable to tie or create logfile'}{
[12] :EndTrap
[13] :EndTrap
[14] nid log'Starting'
[15] :While ServiceState\not=SERVICE_STOPPED
[16] :If ServiceControl\not=0 \diamond
                nid log'ServiceControl=',कServiceControl \diamond :EndIf
[17] :If ServiceState=SERVICE_RUNNING
[18] nid log'Running'
[19] :ElseIf ServiceState=SERVICE_PAUSED
[20] ค Pause application
[21] :EndIf
[22] ServiceControl<0 ค Reset (we only want to log changes)
[23] DDL 10 & Just to prevent busy loop
[24] :EndWhile
[25] DNUNTIE nid
[26] DOFF O
\nabla
```

## Debugging Dyalog Services

Services are run in the background under the auspices of Local System, and not associated with an interactive user. Neither the APL Session nor any GUI components that it creates will be visible on the desktop. This prevents the normal editing and debugging tools from being available.

However, the Dyalog APL Remote Integrated Development environment (RIDE) may be connected to any APL session, including one running as a Windows Service, and provide a debugging environment. For more information, see the Dyalog RIDE User Guide.

## Event Logging

When a service is installed or removed, Dyalog APL records events in the Dyalog APL section of the Applications and Services Logs which can be viewed using the Windows system Event Viewer.

## Causeway Tools

## Overview

SharpPlot has been available for about ten years as a direct replacement for RainPro. It is a conversion of the original APL code into compiled C++ and provides all of the original functionality and more.

SharpPlot is shipped in two forms :

- sharpplot.dll: a Microsoft .Net assembly for Windows, which may also be run on Unix platforms using Mono ${ }^{1}$
- sharpplot. dws: a Dyalog APL workspace that permits SharpPlot to be used on platforms other than .Net

Dyalog recommends upgrading from RainPro to SharpPlot as soon as possible, for a number of reasons :

- It has a more consistent API, and clearer documentation
- It supports more advanced graphics features such as alpha blending and anti-aliased raster graphics.
- It provides better performance (SharpPlot is consistently several times faster than RainPro).
- It provides multi-platform support (RainPro is supported only on windows)
- It includes free support for licensed users, including requests for enhancements

RainPro is still supported on Windows platforms, and bugs will be fixed for commercial users.

## RainPro-to-SharpPlot Transition : SharpRain.dws

SharpRain is a transition tool designed to help Windows users to switch from RainPro to SharpPlot. It is a compatible emulator for RainPro/APL scripts, using SharpPlot/.Net as the backend, and provides better graphics and better performance (generally twice as fast as RainPro).

In addition, it can convert a RainPro script into a SharpPlot script, which will provide further performance improvement (generally 5 to 10 times faster than RainPro)

Further details are provided in sharprain. dws.

[^2]
## Multi-Platform graphics

In Version14.0, SharpPlot is also shipped as an APL workspace (SharpPlot.dws), which will run on all platforms supported by Dyalog.

Raster graphics and custom fonts are not supported, and the API is slightly different from the .Net version. In particular, Properties are accessed through Get*/Set* functions rather than through a variable. These functions provide greater flexibility in terms of the arguments they will accept.

Further details are provided in SharpPlot.dws.
The SharpPlot.dll .Net assembly can still be used on non-Windows platform through Mono.

## Chart Wizard

The chart wizard is a GUI tool to produce arbitrarily complex SharpPlot charts.
It is implemented by the ] chart user command, which takes an APL expression as its argument. The chart wizard will then produce either the chart image, or a script that will generate the same image, for integration into user application.

Sessions can also be saved and loaded for complex chart elaboration.

## Chapter 5:

## Language Reference Changes

## Cells and Sub-arrays

Certain functions and operators operate on particular cells or sub-arrays of an array, which are identified and described as follows.

## K-Cells

A rank-k cell or $k$-cell of an array are terms used to describe a sub-array on the last $k$ axes of the array. Negative $k$ is interpreted as $r+k$ where $r$ is the rank of the array, and is used to describe a sub-array on the leading $\mid k$ axes of an array.

If $X$ is a 3 -dimensional array of shape 234 , the 1 -cells are its 6 rows each of 4 elements; and its 2 -cells are its 2 matrices each of shape 34 . Its 3 -cells is the array in its entirety. Its 0 -cells are its individual elements.

## Major Cells

The major cells of an array X is a term used to describe the sub-arrays on the leading dimension of the array $X$ with shape $1 \downarrow \rho X$. Using the k-cell terminology, the major cells are its ${ }^{-1} 1$-cells.

The major cells of a vector are its elements ( 0 -cells). The major cells of a matrix are its rows (1-cells), and the major cells of a 3-dimensional array are its matrices along the first dimension (2-cells).

## Examples

In the following, the major cells of A are 1979, 1990, 1997, 2007, and 2010; those of B are 'Thatcher', 'Major', 'Blair', 'Brown', and 'Cameron'; and those of $C$ are the four 2-by-3 matrices.

```
    A
1979199019972007 2010
```

    B
    Thatcher
Major
Blair
Brown
Cameron
pB
58

|  | $\square-C+4$ | $23 \mathrm{rr24}$ |
| :---: | :---: | :---: |
| 0 | 12 |  |
| 3 | 45 |  |
| 6 | 78 |  |
| 9 | 1011 |  |

121314
151617
181920
212223

Using the $k$-cell terminology, if $r$ is the rank of the array, its major cells are its $r-1$ cells.

Note that if the right operand $k$ of the Rank Operator $\ddot{\circ}$ is negative, it is interpreted as $0\left\lceil r+k\right.$. Therefore the value ${ }^{-1}$ selects the major cells of the array.
Tally ( $\rho \omega$ ) , 1 \}.

## Examples

$\not \equiv 23$ 4pr10
2
$\not \equiv 2$
1
$\neq \theta$
0
$R \nleftarrow \neq Y$

Y may be any array. R is a simple numeric scalar.
Tally returns the number of major cells of $Y$. This can also be expressed as the length of the leading axis or 1 if $Y$ is a scalar. Tally is equivalent to the function $\{\theta \rho$

Note that $\not \equiv \mathrm{V}$ is useful for returning the length of vector V as a scalar. (In contrast, $\rho \mathrm{V}$ is a one-element vector.)

Index Of $R \leftarrow X_{2} Y$
$Y$ may be any array. $X$ may be any array of rank 1 or more.

## Vector Left Argument

If $X$ is a vector, the result $R$ is a simple integer array with the same shape as $Y$ identifying where elements of $Y$ are first found in $X$. If an element of $Y$ cannot be found in $X$, then the corresponding element of $R$ will be $\square I O+כ \rho X$.

Elements of X and Y are considered the same if $\mathrm{X} \equiv \mathrm{Y}$ returns 1 for those elements.
DIO and DCT/[DCT are implicit arguments of Index Of.

## Examples

DIO 1

41326
'CAT' 'DOG' 'MOUSE'乙'DOG' 'BIRD'
24

## Higher-Rank Left Argument

If $X$ is a higher rank array, the function locates the first occurrence of sub-arrays in $Y$ which match major cells of $X$, where a major cell is a sub-array on the leading dimension of $X$ with shape $1 \downarrow \rho X$. In this case, the shape of the result $R$ is $(1-\rho \rho X) \downarrow \rho Y$.

If a sub-array of $Y$ cannot be found in $X$, then the corresponding element of $R$ will be CIO+כمX.

## Examples

```
    x-3 4\rho_12
    X

Note that the expression ( $y \mathrm{z}$ ) signals a LENGTH ERROR because it looks for major cells in the left argument, whose shape is $514(1 \downarrow \rho y)$, which is not the same as the trailing shape of $x$.
$y x^{x}$
LENGTH ERROR
ylx
$\wedge$

## Mix <br> (DML) <br> $R+\uparrow[K] Y$ or $R \leftrightarrow \square[K] Y$

The symbol chosen to represent Mix depends on the current Migration Level.
If $\square M L<2$, Mix is represented by the symbol: $\uparrow$.
If $\square M L \geq 2$, Mix is represented by the symbol: $د$.
$Y$ may be any array whose items may be uniform in rank and shape, or differ in rank and shape. If the items of $Y$ are non-uniform, they are extended prior to the application of the function as follows:

1. If the items of $Y$ have different ranks, each item is extended in rank to that of the greatest rank by padding with leading 1 s .
2. If the items of $Y$ have different shapes, each is padded with the corresponding prototype to a shape that represents the greatest length along each axis of all items in $Y$.

For the purposes of the following narrative, $y$ represents the virtual item in $Y$ with the greatest rank and shape, with which all other items are extended to conform.
$R$ is an array composed from the items of $Y$ assembled into a higher-rank array with one less level of nesting. $\rho \mathrm{R}$ will be some permutation of ( $\rho \mathrm{Y}$ ), $\rho \mathrm{y}$.

K is an optional axis specification whose value(s) indicate where in the result the axes of $y$ appear. There are three cases:

1. For all values of $\mathrm{CML}, \mathrm{K}$ may be a scalar or 1-element vector whose value is a fractional number indicating the two axes of $Y$ between which new axes are to be inserted for $y$. The shape of $R$ is the shape of $Y$ with the shape $\rho y$ inserted between the LKth and the 「Kth axes of $Y$
2. If $\square M L \geq 2, K$ may be a scalar or 1 -element vector integer whose value specifies the position of the first axis of $y$ in the result. This case is identical to the fractional case where K (in this case) is $\lceil\mathrm{K}$ (in the fractional case).
3. If $\square M L \geq 2, K$ may be a vector, with the same length as $\rho y$, each element of which specifies the position in the result of the corresponding axis of the $y$.

If $K$ is absent, the axes of $y$ appear as the last axes of the result.

## Simple Vector Examples

In this example, the shape of $Y$ is 3 , and the shape of $y$ is 2 . So the shape of the result will be a permutation of 2 and 3 , i.e. in this simple example, either (2 3 ) or ( 32 ).

If $K$ is omitted, the shape of the result is $(\rho Y), \rho y$.

$$
\uparrow\left(\begin{array}{ll}
1 & 2
\end{array}\right)\left(\begin{array}{ll}
3 & 4
\end{array}\right)\left(\begin{array}{ll}
5 & 6
\end{array}\right)
$$

12
34
56
If $K$ is between 0 and 1 , the shape of the result is ( $\rho y$ ) , $\rho Y$ because ( $\rho y$ ) is inserted between the $0^{\text {th }}$ and the $1^{\text {st }}$ axis of the result, i.e. at the beginning.

$$
\uparrow[.5]\left(\begin{array}{ll}
1 & 2
\end{array}\right)\left(\begin{array}{ll}
3 & 4
\end{array}\right)\left(\begin{array}{ll}
5 & 6
\end{array}\right)
$$

135
246
If $K$ is between 1 and 2 , the shape of the result is ( $\rho Y$ ), $\rho \mathrm{y}$ because ( $\rho \mathrm{y}$ ) is inserted between the $1^{\text {st }}$ and $2^{\text {nd }}$ axis of the result, i.e. at the end. This is the same as the case when K is omitted.

```
\uparrow[1.5](1 2)(3 4)(5 6)
```

12
34
56
If $\square M L \geq 2$ an integer $K$ may be used instead (Note that $\supset$ is used instead of $\uparrow$ ).
$\square M L \leftarrow 3$
د(1 2) (3 4) (5 6)
12
34
56
ว[1](1 2) (3 4) (5 6)
135
246

$$
\nu[2](12)(34)(56)
$$

12
34
56

## Shape Extension

If the items of $Y$ are unequal in shape, the shorter ones are extended:
पML $\leftarrow 3$
د(1)(3 4)(5)

10
34
50

$$
د[1](1)(34)(5)
$$

135
040

## More Simple Vector Examples:

    ]box on
    ]box on
    Was OFF
DML -3
ว('andy' 19)('geoff' 37)('pauline' 21)

| andy | 19 |
| :--- | :--- |
| geoff | 37 |
| pauline | 21 |

    د[1]('andy' 19)('geoff' 37)('pauline' 21)
    | andy | geoff | pauline |
| :--- | :--- | :--- |
| 19 | 37 | 21 |

                        ว('andy' 19)('geoff' 37)(c'pauline')
    | andy | 19 |
| :--- | :--- |
| geoff | 37 |
| pauline |  |

Notice that in the last statement, the shape of the third item was extended by catenating it with its prototype.

## Example (Matrix of Vectors)

In the following examples, $Y$ is a matrix of shape (54) and each item of $Y(y)$ is a matrix of shape (32). The shape of the result will be some permutaion of (543 $2)$.

$$
\begin{aligned}
& Y+5 \\
& Y
\end{aligned} 4 \rho(\imath 20) \times c 3 \quad 2 \rho 1
$$

| 1 | 1 | 2 | 2 | 3 | 3 | 4 | 4 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 1 | 2 | 2 | 3 | 3 | 4 | 4 |
| 1 | 1 | 2 | 2 | 3 | 3 | 4 | 4 |
| 5 | 5 | 6 | 6 | 7 | 7 | 8 | 8 |
| 5 | 5 | 6 | 6 | 7 | 7 | 8 | 8 |
| 5 | 5 | 6 | 6 | 7 | 7 | 8 | 8 |
| 9 | 9 | 10 | 10 | 11 | 11 | 12 | 12 |
| 9 | 9 | 10 | 10 | 11 | 11 | 12 | 12 |
| 9 | 9 | 10 | 10 | 11 | 11 | 12 | 12 |
| 13 | 13 | 14 | 14 | 15 | 15 | 16 | 16 |
| 13 | 13 | 14 | 14 | 15 | 15 | 16 | 16 |
| 13 | 13 | 14 | 14 | 15 | 15 | 16 | 16 |
| 17 | 17 | 18 | 18 | 19 | 19 | 20 | 20 |
| 17 | 17 | 18 | 18 | 19 | 19 | 20 | 20 |
| 17 | 17 | 18 | 18 | 19 | 19 | 20 | 20 |

By default, the axes of $y$ appear in the last position in the shape of the result, but this position is altered by specifying the axis K. Notice where the ( 32 ) appears in the following results:

```
    ק>
54 3 2
    O[1]Y
3 254
    \rho_[2]Y
5 3 2 4
    ~[3]Y
5432
    O[4]Y
INDEX ERROR
    \rho\mp@code{[4]Y}
```

Note that $\boldsymbol{\sim}$ [4] $Y$ generates an INDEX ERROR because 4 is greater than the length of the result.

## Example (Vector K)

The axes of $y$ do not have to be contiguous in the shape of the result. By specifying a vector K, they can be distributed. Notice where the 3 and the 2 appear in the following results:

```
    \rho~[1 3]Y
3 5 2 4
    ~[1 4]Y
3 4 2
    \rho[2 4]Y
5 3 4 2
    כ[4 2]Y
5 24 3
```

## Rank Extension

If the items of $Y$ are unequal in rank, the lower rank items are extended in rank by prefixing their shapes with 1s. Each additonal 1 may then be increased to match the maximum shape of the other items along that axis.

$$
\begin{aligned}
& \square M L \leftarrow 3 \\
& Y \leftarrow(1)\left(\begin{array}{llll}
2 & 3 & 4 & 5
\end{array}\right)\left(\begin{array}{ll}
2 & 3 p 10 \times 28
\end{array}\right) \\
& Y
\end{aligned}
$$

| 1 | 2 | 3 | 4 | 5 | 10 | 20 | 30 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 40 | 50 | 60 |  |  |  |  |  |

        Y \(Y\)
    324
$10 \quad 0 \quad 0$
0000
2345
0000
1020300
4050600

In the above example, the first item (1) becomes (1 1 1 1) to conform with the 3rd item which is rank 2. It is then extended in shape to become ( $24 \uparrow 11 \rho 1$ ) to conform with the 2 -row 3 rd item, and 4 -column 2nd item.. Likewise, the 2 nd item becomes a 2 -row matrix, and the 3rd item gains another column.

## Key $R+\{X\} f$ F $Y$

f may be any dyadic function that returns a result．
If $X$ is specified，it is an array whose major cells specify keys for corresponding major cells of $Y$ ．The Key operator目 ${ }^{1}$ applies the function $f$ to each unique key in $X$ and the major cells of $Y$ having that key．

If X is omitted， Y is an array whose major cells represent keys．
In this case，the Key operator applies the function $f$ to each unique key in $Y$ and the elements of $\tau \not \equiv Y$ having that key．$f ⿴ 囗 ⿱ 一 一 ⿱ ⿴ 囗 十 丌$ is the same as $Y \mathrm{f}$ 目 $\imath \neq \mathrm{Y}$ ．

Key is similar to the GROUP BY clause in SQL．

## Example

```
    cards\leftarrow'2' 'Queen' 'Ace' '4' 'Jack'
    suits\leftarrow'Spades' 'Hearts' 'Spades' 'Clubs' 'Hearts'
    suits,[1.5]cards
Spades 2
Hearts Queen
Spades Ace
Clubs 4
Hearts Jack
            suits {\alpha':'\omega}目 cards
Spades : 2 Ace
Hearts : Queen Jack
Clubs : 4
```

In this example，both arrays are vectors so their major cells are their elements．The function $\left\{\alpha^{\prime}:{ }^{\prime} \omega\right\}$ is applied between the unique elements in suits（＇Spades＇ ＇Hearts＇＇Clubs＇）and the elements in cards grouped according to their cor－ responding elements in suits，i．e．（＇2＇＇Ace＇），（＇Queen＇＇Jack＇）and（＇4＇）．

[^3]
## Monadic Example

```
    {\alpha \omega} 目 suits a indices of unique major cells
    Spades 13
    Hearts 2 5
    Clubs 4
    {\alpha,\not\equiv\omega} 目 suits \rho count of unique major cells
Spades 2
Hearts 2
Clubs 1
```

## Further Examples

$x$ is a vector of stock codes，$y$ is a corresponding matrix of values．

```
    px
10
    py
102
    x,y
    IBM 13 75
    AAPL 45 53
    GOOG 21 4
    GOOG 67 67
    AAPL 93 38
    MSFT 51 83
    IBM 3 5
    AAPL 52 67
    AAPL 0 38
    IBM 6 41
```

If we apply the function $\{\alpha \omega\}$ to $x$ and $y$ using the 目 operator，we can see how the rows（its major cells）of $y$ are grouped according to the corresponding elements（its major cells）of $x$ ．

|  | $x\{\alpha$ | $\omega\} ⿴ 囗 ⿱ 一 一 ⿱ ⿴ 囗 十 丌$ |
| :---: | :---: | :---: |
| IBM $y$ |  |  |
| 13 | 75 |  |
|  | 3 | 5 |
|  | 6 | 41 |
| AAPL | 45 | 53 |
|  | 93 | 38 |
|  | 52 | 67 |
|  | 0 | 38 |
| GOOG | 21 | 4 |
|  | 67 | 67 |
| MSFT | 51 | 83 |

More usefully，we can apply the function $\{\alpha(+\not \omega \omega)\}$ ，which delivers the stock codes and the corresponding totals in y ：

|  | $x\{\alpha(++\omega)\}$ 目 $y$ |
| :---: | :---: |
| IBM | 22121 |
| AAPL | 190196 |
| GOOG | 8871 |
| MSFT | 5183 |

There is no need for the function to use its left argument．So to obtain just the totals in y grouped by the stock codes in x ：

$$
22 \quad 121
$$

$$
x\{++\omega\} ⿴ 囗 十
$$

$$
190196
$$

$$
88 \quad 71
$$

$$
51 \quad 83
$$

## Defined Function Example

This example appends the data for a stock into a component file named by the sym－ bol．

```
        \nabla r*stock foo data;fid;file
[1] file↔stock
[2] :Trap 0
[3] fid+file DFTIE O
[4] file OFERASE fid
[5] :EndTrap
[6] fid\leftarrowfile DFCREATE O
[7] r&data DFAPPEND fid
[8] DFUNTIE fid
    \nabla
    x foolly
1 1 1 1
```

## Example

```
    {\alpha \omega} 目 suits ค indices of unique major cells
    Spades 1 3
    Hearts 2 5
    Clubs 4
    {\alpha,\not\equiv\omega} 目 suits A count of unique major cells
Spades 2
Hearts 2
Clubs 1
```

## Another Example

Given a list of names and scores., the problem is to sum the scores for each unique name. A solution is presented first without using the Key operator, and then with the Key operator.

```
    names A 12, some repeat
Pete Jay Bob Pete Pete Jay Jim Pete Pete Jim
Pete Pete
    (unames)\circ.\equivnames
10}00010110\mp@code{0
```

```
0}0
0}000000000100<10100
    scores
66}775\quad71 100 22 10 67 77 55 42 1 1 78 
    b\leftarrow\downarrow(unames)\circ. \equivnames
    ]disp b/`ccr12
```

```
    +/"b/"cscores
399 85 71 109
    ]disp {c\omega}目 names
[\mp@code{1}4~[5
    names {+/\omega}目 scores
399 85 71 109
```

## Rank

 $R \leftarrow\{X\} f \ddot{ } k Y$If X is omitted, f may be any monadic function that returns a result. Y may be any array.

The Rank operator $\ddot{\circ}^{1}$ applies function $f$ successively to the sub-arrays in $Y$ specified by $k$. If $k$ is positive, it selects the $k$-cells of $Y$. If $k$ is negative, it selects the $(r+k)$ cells of $Y$ where $r$ is its rank. If $k$ is ${ }^{-} 1$ it selects the major cells of $Y$.

If $X$ is specified, $f$ may be any dyadic function that returns a result. $Y$ may be any array.

In this case, the Rank operator applies function $f$ successively between the subarrays in $X$ and $Y$ specified by $k$. $k$ is a 2-element integer vector, or a scalar (which is implicitly extended), whose first element selects sub-arrays in $X$ and whose second element selects sub-arrays of Y .

For further information, see Programmer's Guide: Cells and SubarraysCells and Sub-arrays on page 55.

Notice that it is necessary to prevent the right operand $k$ binding to the right argument. This can be done using parentheses e.g. ( $f \ddot{\circ}$ ) Y. The same can be achieved using $\vdash$ because $\ddot{\circ}$ binds tighter to its right operand than $\vdash$ does to its left argument, and $\vdash$ therefore resolves to Identity.

## Monadic Examples

Using enclose (c) as the left operand elucidates the workings of the rank operator.

|  | $Y$ |  |  |  |
| :--- | :--- | :--- | :--- | :---: |
| 36 | 99 | 20 | 5 |  |
| 63 | 50 | 26 | 10 |  |
| 64 | 90 | 68 | 98 |  |
|  |  |  |  |  |
| 66 | 72 | 27 | 74 |  |
| 44 | 1 | 46 | 62 |  |
| 48 | 9 | 81 | 22 |  |
|  |  |  | $\rho Y$ |  |
|  | 3 | 4 |  |  |

234

[^4]

The function $\{(c \Delta \omega) \square \omega\}$ sorts a vector.

```
    {(c\Delta\omega)\\omega} 3 1 4 1 5 9 2 6 5
1123455 6 9
```

The rank operator can be used to apply the function to sub-arrays; in this case to sort the 1 -cells (rows) of a 3-dimensional array.

|  |  | Y |  |  |
| :---: | :---: | :---: | :---: | :---: |
| 36 | 99 | 20 | 5 |  |
| 63 | 50 | 26 | 10 |  |
| 64 | 90 | 68 | 98 |  |
| 66 | 72 | 27 | 74 |  |
| 44 | 1 | 46 | 62 |  |
| 48 | 9 | 81 | 22 |  |
| $(\{(c \Delta \omega) \square \omega\} \ddot{\circ} 1) Y$ |  |  |  |  |
| 5 | 20 | 36 | 99 |  |
| 10 | 26 | 50 | 63 |  |
| 64 | 68 | 90 | 98 |  |
| 27 | 66 | 72 | 74 |  |
| 1 | 44 | 46 | 62 |  |
| 9 | 22 | 48 | 81 |  |

## Dyadic Examples

```
    1020 30 (+\dddot{0 1)3 4\rhoっ12}
10}111121
24 25 26 27
38 39 40 41
```

Using the function $\{\alpha \omega\}$ as the left operand demonstrates how the dyadic case of the rank operator works.

| 10 |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- |
| 10 | 0 | 1 | 20 | 30 |
| 20 | 4 | 5 | 6 | 7 |
| 30 | 8 | 9 | 10 | 11 |

Note that a right operand of ${ }^{-1}$ applies the function between the major cells (in this case elements) of the left argument, and the major cells (in this case rows) of the right argument.

| 10 |  |  |  |  | 20 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 10 | 0 | 1 | 2 | 3 |  |
| 20 | 4 | 5 | 6 | 7 |  |
| 30 | 8 | 9 | 10 | 11 |  |

## Function Trains

## Introduction

A Train is a sequence of 2 or 3 items in an expression which bind together to form a function. Each item in a train may be an array or a function but the right-most item must be a function.

## Forks and Atops

The following trains are supported where $f, g$ and $h$ are functions and $A$ is an array:

$$
\begin{array}{lll}
f & g & h \\
A & g & h \\
& g & h
\end{array}
$$

The 3 -item trains ( f gh ) and ( A gh ) are termed forks while the 2-item train ( g h) is termed an atop. To distinguish the two styles of fork, we can use the terms fghfork or Agh-fork.

## Trains as Functions

A train is syntactically equivalent to a function and so, in common with any other function, may be:

- named using assignment
- applied to or between arguments
- consumed by operators as operands
- and so forth.

In particular, trains may be applied to a single array (monadic use) or between 2 arrays (dyadic use), providing six new constructs.

```
\alpha(f g h)\omega}\leftrightarrow(\alpha f \omega) g (\alpha h \omega) \rho dyadic (fgh) for
\alpha(A g h)\omega}\leftrightarrow\quadA\quadg (\alpha h \omega) \rho dyadic (Agh) for
\alpha( g h)\omega}\leftrightarrow->g g(\alpha h \omega) & dyadic atop
(f g h)\omega\leftrightarrow( f \omega) g ( ( hew) A monadic (fgh) fork
```

## Identifying a Train

For a sequence to be interpreted as a train it must be separated from the argument to which it is applied. This can be done using parentheses or by naming the derived function.

## Example - fork: negation of catenated with reciprocal of

$$
(-, \div) 5
$$

-5 0.2

```
Example - named fork
        negrec}\leftarrow-,
        negrec 5
    -5 0.2
```

Whereas, without these means to identify the sequence as a train, the expression:

$$
-, \div 5
$$

-0. 2
means the negation of the ravel of the reciprocal of 5 .

## Idiom Recognition

Function trains lend themselves to idiom recognition, a technique used to optimise the performance of certain expressions.

## Example

An expression to find the first position in a random integer vector X of a number greater than 999000 is:

```
    X+?1e6\rho1e6
    ( 
```

1704

A function train is not only more concise, it is faster too.

$$
X(\imath \circ 1 \geq) 999000
$$

1704

## Trains of Trains

As a train resolves to a function, a sequences of more than 3 functions represents a train of trains. Function sequences longer than 3 are bound in threes, starting from the right:

```
...fu fv fw fx fy fz -> ...fu(fv fw (fx fy fz))
```

This means that, in the absence of parentheses, a sequence of an odd number of functions resolves to a 3-train (fork) and an even-numbered sequence resolves to a 2-train (atop):

## Examples

$$
6(+,-, \times, \div) 2 \quad \text { ค fork: }(6+2),((6-2),((6 \times 2),(6 \div 2)))
$$

84123

$$
6(\phi+,-, \times, \div) 2 \quad \rho \text { atop: } \phi(6+2), \ldots
$$

31248
]boxing on
Was OFF
,,$+- \times, \div \quad$ a boxed display of fork

ค boxed display of atop

```
            ]boxing -trains=tree
Was -trains=box
    +,-,x,\div \rho boxed (tree) display of fork
+, !- , , \, +, +, +
```

## Binding Strengths

The binding strength between the items of a train is less than that of operand-operator binding. In other words, operators bind first with their function (or array) operands to form derived functions, which may then participate as items in a train.

## Example:

This means that any of the four hybrid tokens $/+\backslash+$ will not be interpreted as a function if there's a function to its left in the train. In order to fix one of these tokens as a replicate or expand function, it must be isolated from the function to its left:

| RANK | $(\imath / \imath) 3$ <br> ERROR | ค $\rightarrow$ ı/ atop $23 \rightarrow$ RANK ERROR |
| :---: | :---: | :---: |
|  | ( $\imath\{\alpha / \omega\} \imath) 3$ | $\rho \rightarrow(\imath 3)\{\alpha / \omega\}(\imath 3) \rightarrow(\imath 3) /(\imath 3)$ |
| 122 | 333 |  |
|  | ( 2 (/ 0 - ) て) 3 |  |
| 122 | 333 |  |
|  | (2/ヶ)3 | a Agh-fork is OK |

## File Properties <br> R $+X$ DFPROPS $Y$

## Access Code 1 (to read) or 8192 (to change properties)

DFPROPS reports and sets the properties of a component file.
Y must be a simple integer scalar or 1 or 2-element vector containing the file tie number followed by an optional passnumber. If the passnumber is omitted, it is assumed to be 0 .
$X$ must be a simple character scalar or vector containing one or more valid Identifiers listed in the table below, or a 2-element nested vector which specifies an Identifier and a (new) value for that property. To set new values for more than one property, X must be is a vector of 2-element vectors, each of which contains an Identifier and a (new) value for that property.

If the left argument is a simple character array, the result $R$ contains the current values for the properties identified by $X$. If the left argument is nested, the result $R$ contains the previous values for the properties identified by $X$.

| Identifier | Property | Description / Legal Values |
| :---: | :---: | :---: |
| S | File Size (read only) | $32=$ Small-span Component Files (<4GB) <br> $64=$ Large-span Component Files |
| E | Endian-ness (read only) | $\begin{aligned} & 0=\text { Little-endian } \\ & 1=\text { Big-endian } \end{aligned}$ |
| U | Unicode | $0=$ Characters will be written as type 82 arrays <br> $1=$ Characters will be written as Unicode arrays |
| J | Journaling | $0=$ Disable Journaling <br> $1=$ Enable APL crash proof Journaling <br> 2 = Enable System crash proof Journaling; repair needed on recovery <br> 3 = Enable full System crash proof Journaling |
| C | Checksum | $\begin{aligned} & 0=\text { Disable checksum } \\ & 1=\text { Enable checksum } \end{aligned}$ |
| Z | Compression | $\begin{aligned} & 0=\text { Disable compression } \\ & 1=\text { Enable compression } \end{aligned}$ |

The default properties for a newly created file are as follows:

- $\mathrm{S}=64$
- $\mathrm{U}=1$ (in Unicode Edition) or 0 (in Classic Edition)
- $\mathrm{J}=1$
- $\mathrm{C}=1$
- $\mathrm{Z}=0$
- E depends upon the computer architecture.

Note that the defaults for C and J can be overridden by calling DF CREATE via the Variant operator B. For further information, see File Create on page 80.

## Journaling Levels

Level 1 journaling (APL crash-proof) automatically protects a component file from damage in the event of abnormal termination of the APL process. The file state will be implicitly committed between updates and an incomplete update will automatically be rolled forward or back when the file is re-tied. In the event of an operating system crash the file may be more seriously damaged. If checksum was also enabled it may be repaired using DF CHK but some components may be restored to a previous state or not restored at all.

Level 2 journaling (system crash-proof - repair needed on recovery) extends level 1 by ensuring that a component file is fully repairable using DFCHK with no component loss in the event of an operating system failure. If an update was in progress when the system crashed the affected component will be rolled back to the previous state. Tying and modifying such a file without first running DFCHK may however render it un-repairable.

Level 3 journaling (system crash-proof) extends level 2 by protecting a component file from damage in the event of abnormal termination of the APL process and also the operating system. Rollback of an incomplete update will be automatic and no explicit repair will be needed.

Enabling journaling on a component file will reduce performance of file updates; higher journaling levels have a greater impact.

Journaling levels 2 and 3 cannot be set unless the checksum option is also enabled.
The default level of journaling may be changed using the APL_FCREATE_ PROPS_J parameter (see User Guide).

## Checksum Option

The checksum option is enabled by default. This enables a damaged file to be repaired using DFCHK. It will however reduce the performance of file updates slightly and result in larger component files. The default may be changed using the APL_FCREATE_PROPS_C parameter (See User Guide).

Enabling the checksum option on an existing non-empty component file will result in all previously written components without a checksum being check-summed and converted. This operation which will take place when DFPROPS is changed, may not therefore be instantaneous.

Journaling and checksum settings may be changed at any time a file is exclusively tied.

## Example

tn*'myfile64' DFCREATE 0
'SEUJ' DFPROPS tn
64010
The following expression disables Unicode and switches Journaling on. The function returns the previous settings:

## 10

```
('U' O)('J' 1) DFPROPS tn
```

Note that to set the value of just a single property, the following two statements are equivalent:

```
'J' 1 DFPROPS tn
(.c'J' 1) DFPROPS tn
```

Properties may be read by a task with DFREAD permission (access code 1), and set by a task with DF STAC access (8192). To set the value of the Journaling property, the file must be exclusively tied.

## Recommendation

It is recommended that all component files are protected by a minimum of Level 1 Journalling and have Checksum enabled.

Unprotected files should only be used:

- for temporary work files where speed is paramount and integrity a secondary issue
- or where compatibility with Versions of Dyalog prior to Version 12.0 is required

This recommendation is given for the following reasons:

- Unprotected files are easily damaged by abnormal termination of the interpreter
- They cannot be repaired using DFCHK
- They do not support DFHIST
- They are not well supported by the Dyalog File Server (DFS)
- They do not support compression of components
- Additional features added in future may not be supported

## Compression Option

Components are compressed using the LZ4 compressor which delivers a medium level of compression, but is considered to be very fast compared to other algorithms.

Compression is intended to deliver a performance gain reading and writing large components on fast computers with slow (e.g. network) file access. Conversely, on a slow computer with fast file access compression may actually reduce read/write performance. For this reason it is optional at the component level.

The default for the ' $Z$ ' property is 0 which means no compression; 1 means compression. When written, components are compressed or not according to the current value of the ' $Z$ ' property. Changing this property does not change any components already in the file.

A component file may therefore contain a mixture of normal and compressed components. Note that only the data in file components are compressed, the file access matrix and other header information is not compressed.

When read, compressed components are decompressed regardless of the value of the ' Z ' property.

An exclusive tie is not needed to change the file property.
Compression is not supported for files in which both Journalling and Checksum are disabled.

## File Create

## $\{R\}+X$ DFCREATE $Y$

$Y$ must be a simple integer scalar or a 1 or 2 element vector. The first element is the file tie number. The second element, if specified, must be $64^{1}$.

The file tie number must not be the tie number associated with another tied file.
$X$ must be either
a. a simple character scalar or vector which specifies the name of the file to be created. See User Guide for file naming conventions under UNIX and Windows.
b. a vector of length 1 or 2 whose items are:
i. a simple character scalar or vector as above.
ii. an integer scalar specifying the file size limit in bytes.

The newly created file is tied for exclusive use.
The shy result of CFCREATE is the tie number of the new file.

## Automatic Tie Number Allocation

A tie number of 0 as argument to a create or tie operation, allocates, and returns as an explicit result, the first (closest to zero) available tie number. This allows you to simplify code. For example:
from:

$$
\begin{array}{ll}
\text { tie } \leftarrow 1+\lceil/ 0 \text {, } \mathrm{DFNUMS} & \text { A With next available number, } \\
\text { file पFCREATE tie } & \text { a } . . \text { create file. }
\end{array}
$$

to:

$$
\text { tie } \leftarrow \text { file DFCREATE } 0 \text { ค Create with first available.. }
$$

## Examples

[^5]
## File Properties

DFCREATE allows you to specify propeties for the newly created file via the variant operator $\square_{\text {used with the following options: }}$

- 'J' - journaling level; a numeric value.
- 'C' - checksum level; 0 or 1 .
- 'Z' - compression; 0 or 1 .

The Principal Option is neither ' J ' nor ' C ' - but a combination as follows:

- 0 -sets ('J' 0) ('C' 0)
- 1-sets ('J' 1) ('C' 1)
- 2 -sets ('J' 2) ('C' 1)
- 3-sets ('J' 3) ('C' 1)

## Examples

'newfile' (口fCREATEG3) 0
1
'SEUJCZ' DFPROPS 1
6401310
Alternatively:

```
JFCREATE&-पFCREATE : 3
```

will name a variant of DF CREATE which will create component file with level 3 journaling, and checksum enabled. Then:

$$
\text { 'newfile'JFCREATE } 0
$$

1

## File Read Components <br> R-DFREAD Y

## Access code 1

Y is a 2 or 3 item vector containing the file tie number, the component number(s), and an optional passnumber. If the passnumber is omitted it is assumed to be zero. All elements of Y must be integers.

The second item in $Y$ may be scalar which specifies a single component number or a vector of component numbers. If it is a scalar, the result is the value of the array that is stored in the specified component on the tied file. If it is a vector, the result is a vector of such arrays.

Note that any invocation of पFREAD is an atomic operation. Thus if compnos is a vector, the statement:

DFREAD tie compnos passno
will return the same result as:
\{DFREAD tie $\omega$ passno\}"compnos
However, the first statement will, in the case of a share-tied file, prevent any potential intervening file access from another user (without the need for a DF HOLD). It will also perform slightly faster, especially when reading from a share-tied file.

## Examples

pSALES*-DFREAD 1241
3212

```
GetFile<{Dio<0 A Extract contents.
    tie+\omega पfstie 0 a new tie number.
    fm to\leftarrow2\uparrow\fsize tie a first and next component.
    cnos&fm+rto-fm & vector of component nos.
    cvec*-पfread tie cnos \rho vector of components.
    cvec{\alpha}\squarefuntie tie \rho ... untie and return.
}
```

## File Check and Repair <br> R-\{X\} DFCHK Y

DFCHK validates and repairs component files, and validates files associated with external variables, following an abnormal termination of the APL process or operating system.

Y must be a simple character scalar or vector which specifies the name of the file to be exclusively checked or repaired. For component files, the file must be named in accordance with the operating system's conventions, and may be a relative or absolute pathname. The file must exist and must not be tied. For files associated with external variables, any filename extension must be specified even if DXT would not require it. The file must exist and must not currently be associated with an external variable.

Options forDFCHK are specified using the Variant operator ${ }^{\text {B }}$ or by the optional left argument $X$. The former is recommended but the older mechanism using the left argument is still supported.

In either case, the default behaviour is as follows:

1. If the file appears to have been cleanly untied previously, return $\theta$, i.e. report that the file is good.
2. Otherwise, validate the file and return the appropriate result. If the file is corrupt, no attempt is made to repair it.

The result $R$ is a vector of the numbers of missing or damaged components. $R$ may include non-positive numbers of "pseudo components" that indicate damage to parts of the file other than in specific components:

| 0 | ACCESS MATRIX. |
| :--- | :--- |
| -1 | Free-block tree. |
| -2 | Component index tree. |

Other negative numbers represent damage to the file metadata; this set may be extended in the future.

## Specifying options using Variant

Using Variant, the options are as follows:

- Task
- Repair
- Force

Rebuild causes the file indices to be discarded and rebuilt. Repair only takes place on files which have been checked and found to be damaged. It involves a rebuild, but that only takes place if it is needed. Note that Repair and Force only apply if Task is 'Scan'.

## Task

| Scan | causes the file to be checked and optionally repaired (see <br> 'Repair' below) |
| :--- | :--- |
| Rebuild | causes the file to be unconditionally rebuilt |

## Repair (principle option)

| 0 | do not repair |
| :--- | :--- |
| 1 | causes the file to be repaired if damage is found |

## Force

| 0 | do not validate the file if it appears to have been properly <br> closed |
| :--- | :--- |
| 1 | validate the file even if it appears to have been properly closed |

Default values are highlighted thus in the above tables.

## Examples

To check a file and attempt to fix it if damage is found:
(DFCHK (1)'suspect.dcf'
To forcibly check a file and attempt to fix it if damage is found:
(DFCHK 日 ('Repair' 1)('Force'1))'suspect.dcf'

## Specifying options using a left argument

Using the optional left-argument, X must be a vector of zero or more character vectors from among 'force', 'repair' and 'rebuild', which determine the detailed operation of the function. Note that these options are case-insensitive.

- If $X$ contains 'force ', DFCHK will validate the file even if it appears to have been cleanly untied.
- If $X$ contains 'repair', DFCHK will repair the file, following validation, if it appears to be damaged. This option may be used in conjunction with 'force'.
- If $X$ contains 'rebuild', DFCHK will repair the file unconditionally.

Following a check of the file, a non-null result indicates that the file is damaged.
Following a repair of the file, the result indicates those components that could not be recovered. Un-recovered components will give a FILE COMPONENT DAMAGED error if read but may be replaced without error.

Repair can recover only check-summed components from the file, i.e. only those components that were written with the checksum option enabled (see File Properties on page 76).

Following an operating system crash, repair may result in one or more individual components being rolled back to a previous version or not recovered at all, unless Journaling levels 2 or 3 were also set when these components were written.

## XML Convert <br> $R+\{X\}$ XXML $Y$

DXML converts an XML string into an APL array or converts an APL array into an XML string.

Options for DXML are specified using the Variant operator 目 or by the optional left argument $X$. The former is recommended but the older mechanism using the left argument is still supported.

For conversion from XML, Y is a character vector containing an XML string. The result $R$ is a 5 column matrix whose columns are made up as follows:

| Column | Description |
| :--- | :--- |
| 1 | Numeric value which indicates the level of nesting |
| 2 | Element name, other markup text, or empty character vector when <br> empty |
| 3 | Character data or empty character vector when empty |
| 4 | Attribute name and value pairs, $\left(\begin{array}{ll}0 & 2 \rho c^{\prime}\end{array}\right)$ when empty |
| 5 | A numeric value which indicates what the row contains |

The values in column 5 have the following meanings:

| Value | Description |
| :--- | :--- |
| 1 | Element |
| 2 | Child element |
| 4 | Character data |
| 8 | Markup not otherwise defined |
| 16 | Comment markup |
| 32 | Processing instruction markup |

## Example

$$
\begin{aligned}
& x \leftarrow^{\prime}<x m l><d o c u m e n t ~ i d=" 001 ">A n \text { introduction to } X M L ' \\
& x, \leftarrow \text { </document></xml>' } \\
& \text { Jdisplay } v+\square X M L \times
\end{aligned}
$$

For conversion to $\mathrm{XML}, \mathrm{Y}$ is a 3,4 or 5 column matrix and the result R is a character vector. The columns of $Y$ have the same meaning as those described above for the result of converting from XML.

## Example

DXML v
<xml>
<document id="001">An introduction to XML</document> </xml>

## Introduction to XML and Glossary of Terms

XML is an open standard, designed to allow exchange of data between applications. The full specification ${ }^{1}$ describes functionality, including processing directives and other directives, which can transform XML data as it is read, and which a full XML processor would be expected to handle.

The DXML function is designed to handle XML to the extent required to import and export APL data. It favours speed over complexity - some markup is tolerated but largely ignored, and there are no XML query or validation features. APL applications which require processing, querying or validation will need to call external tools for this, and finally call DXML on the resulting XML to perform the transformation into APL arrays.

XML grammar such as processing instructions, document type declarations etc. may optionally be stored in the APL array, but will not be processed or validated. This is principally to allow regeneration of XML from XML input which contains such structures, but an APL application could process the data if it chose to do so.

The XML definition uses specific terminology to describe its component parts. The following is a summary of the terms used in this section:

## Character Data

Character data consists of free-form text. The free-form text should not include the characters '>', '<' or ' $\&$ ', so these must be represented by their entity references ('\>', '\<' and '\&' respectively), or numeric character references.

## Entity References and Character References

Entity references are named representations of single characters which cannot normally be used in character data because they are used to delimit markup, such as \> for ' $>$ '. Character references are numeric representations of any character, such as \&\#20; for space. Note that character references always take values in the Unicode code space, regardless of the encoding of the XML text itself.

IXML converts entity references and all character references which the APL character set is able to represent into their character equivalent when generating APL array data; when generating XML it converts any or all characters to entity references as needed.

There is a predefined set of entity references, and the XML specification allows others to be defined within the XML using the <! ENTITY > markup. IXML does not process these additional declarations and therefore will only convert the predefined types.

[^6]
## Whitespace

Whitespace sequences consist of one or more spaces, tabs or line-endings. Within character data, sequences of one or more whitespace characters are replaced with a single space when this is enabled by the whitespace option. Line endings are represented differently on different systems ( $0 x 0 \mathrm{D} 0 \mathrm{x} 0 \mathrm{~A}, 0 \mathrm{x} 0 \mathrm{~A}$ and 0 x 0 D are all used) but are normalized by converting them all to 0 x 0 A before the XML is parsed, regardless of the setting of the whitespace option.

## Elements

An element consists of a balanced pair of tags or a single empty element tag. Tags are given names, and start and end tag names must match.

An example pair of tags, named TagName is

```
<TagName></TagName>
```

This pair is shown with no content between the tags; this may be abbreviated as an empty element tag as
<TagName/>
Tags may be given zero or more attributes, which are specified as name/value pairs; for example
<TagName AttName="AttValue">
Attribute values may be delimited by either double quotes as shown or single quotes (apostrophes); they may not contain certain characters (the delimiting quote, ' $\&$ ' or ' $<$ ') and these must be represented by entity or character references.

The content of elements may be zero or more mixed occurrences of character data and nested elements. Tags and attribute names describe data, attribute values and the content within tags contain the data itself. Nesting of elements allows structure to be defined.

Because certain markup which describes the format of allowable data (such as element type declarations and attribute-list declarations) is not processed, no error will be reported if element contents and attributes do not conform to their restricted declarations, nor are attributes automatically added to tags if not explicitly given.

Attributes with names beginning $\mathbf{x m l}$ : are reserved. Only $\mathbf{x m l}$ :space is treated specially by $\quad$ XML. When converting both from and to XML, the value for this attribute has the following effects on space normalization for the character data within this element and child elements within it (unless subsequently overridden):

- default - space normalization is as determined by the whitespace option.
- preserve - space normalization is disabled - all whitespace is preserved as given.
- any other value - rejected.

Regardless of whether the attribute name and value have a recognised meaning, the attribute will be included in the APL array / generated XML. Note that when the names and values of attributes are examined, the comparisons are case-sensitive and take place after entity references and character references have been expanded.

## Comments

Comments are fully supported markup. They are delimited by '<!--' and '-->' and all text between these delimiters is ignored. This text is included in the APL array if markup is being preserved, or discarded otherwise.

## CDATA Sections

CDATA Sections are fully supported markup. They are used to delimit text within character data which has, or may have, markup text in it which is not to be processed as such. They and are delimited by ' $<$ ![CDATA[' and ‘]]>'. CDATA sections are never recorded in the APL array as markup when XML is processed - instead, that data appears as character data. Note that this means that if you convert XML to an APL array and then convert this back to XML, CDATA sections will not be regenerated. It is, however, possible to generate CDATA sections in XML by presenting them as markup.

## Processing Instructions

Processing Instructions are delimited by ' $<\&$ ' and ' $\&>$ ' but are otherwise treated as other markup, below.

## Other markup

The remainder of XML markup, including document type declarations, XML declarations and text declarations are all delimited by ' $<$ !' and ' $>$ ', and may contain nested markup. If markup is being preserved the text, including nested markup, will appear as a single row in the APL array. DXML does not process the contents of such markup. This has varying effects, including but not limited to the following:

- No validation is performed.
- Constraints specified in markup such element type declarations will be ignored and therefore syntactically correct elements which fall outside their constraint will not be rejected.
- Default attributes in attribute-list declarations will not be automatically added to elements.
- Conditional sections will always be ignored.
- Only standard, predefined, entity references will be recognized; entity declarations which define others entity references will have no effect.
- External entities are not processed.

## Conversion from XML

- The level number in the first column of the result $R$ is 0 for the outermost level and subsequent levels are represented by an increase of 1 for each level. Thus, for
- <xml><document id="001">An introduction to XML </document></xml>
- The $x m l$ element is at level 0 and the document id element is at level 1 . The text within the document id element is at level 2.
- Each tag in the XML contains an element name and zero or more attribute name and value pairs, delimited by ' $<$ ' and ' $>$ ' characters. The delimiters are not included in the result matrix. The element name of a tag is stored in column 2 and the attribute(s) in column 4.
- All XML markup other than tags are delimited by either ' $<$ !' and ' $>$ ', or ' $<$ ?' and ' $>$ ' characters. By default these are not stored in the result matrix but the markup option may be used to specify that they are. The elements are stored in their entirety, except for the leading and trailing ' $<$ ' and ' $>$ ' characters, in column 2. Nested constructs are treated as a single block. Because the leading and trailing ' $<$ ' and ' $>$ ' characters are stripped, such entries will always have either '!' or ' $\&$ ' as the first character.
- Character data itself has no tag name or attributes. As an optimisation, when character data is the sole content of an element, it is included with its parent rather than as a separate row in the result. Note that when this happens, the level number stored is that of the parent; the data itself implicitly has a level number one greater.
- Attribute name and value pairs associated with the element name are stored in the fourth column, in an ( $\left.\begin{array}{lll}x & 2\end{array}\right)$ matrix of character values, for the $n$ (including zero) pairs.
- Each row is further described in the fifth column as a convenience to simplify processing of the array (although this information could be deduced). Any given row may contain an entry for an element, character data, markup not otherwise defined, a comment or a processing instruction. Furthermore, an element will have zero or more of these as children. For all types except elements, the value in the fifth column is as shown above. For elements, the value is computed by adding together the value of the row itself (1) and those of its children. For example, the value for a row for an element which contains one or more sub-elements and character data is $7-$ that is 1 (element) +2 (child element) +4 (character data). It should be noted that:
- Odd values always represent elements. Odd values other than 1 indicate that there are children.
- Elements which contain just character data (5) are combined into a single row as noted previously.
- Only immediate children are considered when computing the value. For example, an element which contains a sub-element which in turn contains character data does not itself contain the character data.
- The computed value is derived from what is actually preserved in the array. For example, if the source XML contains an element which contains a comment, but comments are being discarded, there will be no entry for the comment in the array and the fifth column for the element will not indicate that it has a child comment.

## Conversion to XML

Conversion to XML takes an array with the format described above and generates XML text from it. There are some simplifications to the array which are accepted:

- The fifth column is not needed for XML generation and is effectively ignored. Any numeric values are accepted, or the column may be omitted altogether.
- If there are no attributes in a particular row then the ( $02 \rho c^{\prime}$ ) may be abbreviated as $\theta$ (zilde). If the fifth column is omitted then the fourth column may also be omitted altogether.
- Data in the third column and attribute values in the fourth column (if present) may be provided as either character vectors or numeric values. Numeric values are implicitly formatted as if DPP was set to 17 .

The following validations are performed on the data in the array:

- All elements within the array are checked for type.
- Values in column 1 must be non-negative and start from level 0 , and the increment from one row to the next must be $\leq+1$.
- Tag names in column 2 and attribute names in column 4 (if present) must conform to the XML name definition.

Then, character references and entity references are emitted in place of characters where necessary, to ensure that valid XML is generated. However, markup, if present, is not validated and it is possible to generate invalid XML if care in not taken with markup constructs.

## Options

There are 3 options which may be specified using the Variant operator B (recom- $^{\text {a }}$ ) mended) or by the optional left argument $X$ (retained for backwards compatibility). The names are different and are case-sensitive; they must be spelled exactly as shown below.

| Option names for Variant | Option names for left argument |
| :--- | :--- |
| Whitespace | whitespace |
| Markup | markup |
| UnknownEntity | unknown-entity |

The values of each option are tabulated below. In each case the value of the option for Variant is given first, followed by its equivalent for the optional left argument in brackets; e.g. UnknownEntity (unknown-entity).

Note that the default value is shown first, and that the option names and values are case-sensitive.

If options are specified using the optional left argument, $X$ specifies a set of option/value pairs, each of which is a character vector. $X$ may be a 2 -element vector, or a vector of 2-element character vectors. In the examples below, this method is illustrated by the equivalent expression written as a comment, following the recommended approach using the Variant operator $\mathrm{B}^{\mathrm{B}}$ i.e.

$$
\begin{aligned}
& \text { ]display (DXMLQ'Whitespace' 'Strip')eg } \\
& \text { ( } \quad \text { 'whitespace' 'strip' DXML eg }
\end{aligned}
$$

Errors detected in the input arrays or options will all cause DOMAIN ERROR.

## Whitespace (whitespace)

When converting from XML Whitespace specifies the default handling of white space surrounding and within character data. When converting to XML
Whitespace specifies the default formatting of the XML. Note that attribute values are not comprised of character data so white space in attribute values is always preserved.

| Converting from XML |  |
| :--- | :--- |
| $\begin{array}{l}\text { Strip } \\ \text { (strip) }\end{array}$ | $\begin{array}{l}\text { All leading and trailing whitespace sequences are removed; } \\ \text { remaining whitespace sequences are replaced by a single } \\ \text { space character }\end{array}$ |
| $\begin{array}{l}\text { Trim } \\ \text { (trim) }\end{array}$ | $\begin{array}{l}\text { All leading and trailing whitespace sequences are removed; } \\ \text { all remaining white space sequences are handled as preserve }\end{array}$ |
| $\begin{array}{l}\text { Preserve } \\ \text { (preserve) }\end{array}$ | $\begin{array}{l}\text { Whitespace is preserved as given except that line endings are } \\ \text { represented by Linefeed (■uCs 10) }\end{array}$ |
| Converting to XML |  |
| $\begin{array}{l}\text { Strip } \\ \text { (strip) }\end{array}$ | $\begin{array}{l}\text { All leading and trailing whitespace sequences are removed; } \\ \text { remaining whitespace sequences within the data are replaced } \\ \text { by a single space character. XML is generated with } \\ \text { formatting and indentation to show the data structure }\end{array}$ |
| $\begin{array}{l}\text { Trim } \\ \text { (trim) }\end{array}$ | $\begin{array}{l}\text { Synonymous with strip }\end{array}$ |
| Preserve |  |
| (preserve) |  | \(\left.\begin{array}{l}White space in the data is preserved as given, except that line <br>

endings are represented by Linefeed ( \square generated with no formatting and indentation other than that <br>
which is contained within the data\end{array}\right]\)

```
        ]display eg
<xml>
    <a>
        Data1
        <!-- Comment -->
        Data2
        <b> Data3 </b>
        Data4
        <c att="val"/>
    </a>
</xml>
```

]display (口XMLG'Whitespace' 'Strip')eg
ค 'whitespace' 'strip' $\square X M L$ eg

]display (DXMLD'Whitespace' 'Preserve')eg
a 'whitespace' 'preserve' DXML eg

## Markup (markup)

When converting from XML, Markup determines whether markup (other than entity tags) appears in the output array or not. When converting to XML Markup has no effect.

| Converting from XML |  |
| :--- | :--- |
| Strip <br> (strip) | Markup data is not included in the output array |
| Preserve <br> (preserve) | $\begin{array}{l}\text { Markup text appears in the output array, without the leading } \\ \\ \hline\end{array}$ and trailing ' $>$ ' in the tag (2nd $)$ column |

## ]display eg

```
<xml>
    <a>
        Data1
        <!-- Comment -->
        Data2
        <b> Data3 </b>
        Data4
        <c att="val"/>
    </a>
</xml>
```

## UnknownEntity (unknown-entity)

When converting from XML, this option determines what happens when an unknown entity reference, or a character reference for a Unicode character which cannot be represented as an APL character, is encountered. In Classic versions of Dyalog APL that is any Unicode character which does not appear in DAVU. When converting to XML, this option determines what happens to Esc characters (DUCS 27) in data.

| Converting from XML |  |
| :--- | :--- |
| Replace <br> (replace) | The reference is replaced by a single '?' character |
| Preserve <br> (preserve) | The reference is included in the output data as given, but <br> with the leading ' \&' replaced by Esc ([UCS 27) |
| Converting to XML |  |
| Replace <br> (replace) | Esc (ZUCS 27) is preserved |
| Preserve <br> (preserve) | Esc (ZUCS 27) is replaced by '\&' |

Y may be any non-negative integer array. R has the same shape as Y at each depth.
For each positive element of $Y$ the corresponding element of $R$ is an integer, pseudorandomly selected from the integers $\imath Y$ with each integer in this population having an equal chance of being selected.

For each zero element of $Y$, the corresponding element of $R$ is a pseudo-random float-ing-point value in the range $0-1$, but excluding 0 and 1, i.e. $(0<R[I]<1)$.

DIO and DRL are implicit arguments of Roll. A side effect of Roll is to change the value of $\square R L$.

Note that different random number generators are available; see 16807 I for more information.

## Chapter 6:

## I-Beam Reference Changes

## Summary

In the following tables, $A$ is an integer that specifies the type of operation to be performed.

I-Beam functionality removed from Version 14.0.

| A | Derived Function |
| :--- | :--- |
| 685 | UNIX only: core to aplcore |

I-Beam functionality extended in Version 14.0.

| A | Derived Function |
| :--- | :--- |
| 1111 | Number of Threads/Virtual Processors |

I-Beam functionality added to Version 14.0.

| $\mathbf{A}$ | Derived Function |
| :--- | :--- |
| 8 | Inverted Table Index-of |
| 181 | Unsqueezed Type |
| 219 | Compress/Decompress Vector of Short Integers |
| 220 | Serialise/Deserialise Array |
| 1159 | Update Function Time and User Stamp |
| 2002 | Specify Workspace Available |

| A | Derived Function |
| :--- | :--- |
| 2015 | Data Binding |
| 2022 | Flush Session Caption |
| 2023 | Close all Windows |
| 2400 | Set Workspace Save Options |
| 2401 | Expose Root Properties |

## Inverted Table Index Of <br> $R \leftarrow X(8 I) Y$

This function computes $X$ index-of $Y\left(\right.$ viz. $\left.X_{\imath} Y\right)$ where $X$ and $Y$ are compatible inverted tables. $R$ is the indices of $Y$ in $X$.

An inverted table is a (nested) vector all of whose items have the same number of major cells. That is, $1=\rho \rho \omega$ and $(\not \equiv \supset \omega)=\neq{ }^{*} \omega$. An inverted table representation of relational data is more efficient in time and space than other representations.

The following is an example of an inverted table:

```
X<(10 30Пa) (r10) 'metalepsis'
X
```

| ABC | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | metalepsis |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| DEF |  |  |  |  |  |  |  |  |  |  |  |
| GHI |  |  |  |  |  |  |  |  |  |  |  |
| JKL |  |  |  |  |  |  |  |  |  |  |  |
| MNO |  |  |  |  |  |  |  |  |  |  |  |
| PQR |  |  |  |  |  |  |  |  |  |  |  |
| STU |  |  |  |  |  |  |  |  |  |  |  |
| VWX |  |  |  |  |  |  |  |  |  |  |  |
| YZA |  |  |  |  |  |  |  |  |  |  |  |
| BCD |  |  |  |  |  |  |  |  |  |  |  |

Using inverted tables, it is often necessary to perform a table look-up to find the "row" indices of one in another. Suppose there is a second table $Y$ :

```
Y\leftarrow(cc3 1 4 1 5 9)]`X
Y
GHI 3 1 4 1 5 9 tmamli
```

ABC
JKL
ABC
MNO
YZA

To compute the indices of $Y$ in $X$ using dyadic $\imath$, it is necessary to first un-invert each of the tables in order to create nested matrices that $\imath$ can handle.

```
    unvert \leftarrow {\phi\uparrowc\ddot{o-1"\omega}\omega}
    unvert X
\begin{tabular}{|l|l|l|}
\hline ABC & 0 & m \\
\hline DEF & 1 & e \\
\hline GHI & 2 & t \\
\hline JKL & 3 & a \\
\hline MNO & 4 & l \\
\hline PQR & 5 & e \\
\hline STU & 6 & p \\
\hline VWX & 7 & s \\
\hline YZA & 8 & i \\
\hline BCD & 9 & s \\
\hline
\end{tabular}
```

```
    (unvert X) \imath (unvert Y)
```

    (unvert X) \imath (unvert Y)
    314159

```
314159
```

Each un-inverted table requires considerably more workspace than its inverted form, so if the inverted tables are large, this operation is potentially expensive in terms of both time and workspace.

8 I is an optimised version of the above expression.

$$
X(8 I) Y
$$

314159

## Unsqueezed Type $R+181$ I $Y$

$Y$ is any array.
The result $R$ is an integer scalar containing an integer value which indicates the type of the array.

181 I is functionally identical to monadic CDR, except that no attempt is made to squeeze the data into smaller data types. पDR always attempts to squeeze the data; 181 I does not, but if a workspace compaction occurs during execution of 181 I, the data may still be squeezed before the type is identified.

## Example

```
\squaredr 1^1 1000
```

11
(181ェ) $1 \uparrow 11000$
163

## Compress Vector of Short Integers $\quad R \leftarrow X(219 I) Y$

In this section, the term sint_vector is used to refer to a simple integer vector whose items are all in the range -128 to 127 i.e. they are type 83.

In most cases this I-Beam functionality will be used in conjunction with 220 (Serialise/Deserialise Array). However, it may be possible to pass the raw compressed data to and from other applications.
$X$ specifies the operation to be performed, either compression or decompression, the compression library to be used, and any optional parameters. $Y$ contains the data to be operated on.

## Compression

$Y$ must be a sint_vector.
$R$ is a two item vector, each of which is a sint_vector. $R[1]$ describes the compression, and $R[2]$ contains the raw data which is the result of applying the compression library to the input data Y .
$X$ is specified as follows:

| $X[1]$ | $X[2]$ | Compression Library |
| :--- | :--- | :--- |
| 1 | $\mathrm{n} / \mathrm{a}$ | LZ4 |
| 2 | $0 . .9$ | zlib |
| 3 | $0 . .9$ | gzip |

If LZ4 compression is required, then $X$ must either be a scalar or a one element vector. Otherwise, X[2], if present, specifies the compression level; higher numbers produce better compression, but take longer.

## Decompression

$R$ is a sint_vector, containing the output of applying the decompression library to the input data, Y .

If $X$ is a scalar or a one item vector, and has the value 0 , then $Y$ must be a vector of two items which is the result of previously calling 219 I to compress a sint_vector.

Otherwise, X is a scalar or one or two element vector. The first element of X must be one of the following values.

| $X[1]$ | Compression Library |
| :--- | :--- |
| -1 | LZ4 |
| -2 | zlib |
| -3 | gzip |

The second, optional, element of $X$ specifies the length of the uncompressed data. Its presence results in a more efficient use of the compression library.
$X$ may not be a two item vector whose first item has the value 0 .

```
Examples
    sint<{\omega-256\times\omega>127}
        utf8<'UTF-8'o口ucs
        str}\mp@subsup{\leftarrow}{}{\prime}\mathrm{ empty* - '
        -v*sint utf8 str
101 109 112 116 121 - 30-122 -112 -30 -115 -84
        -comp+1 (219I) v
8-55 1 0 0 0 0 0 11 -80 101 109 112 116 121 -30-122 -112
-30-115 -84
    utf8 256| O(219I)comp
empty}+
    utf8 256| -1(219I)2כcomp
empty*0
```

## Serialise/Deserialise Array <br> $R \leftarrow X(220 I) Y$

In this section, the term sint_vector is used to refer to a simple integer vector whose items are all in the range -128 to 127 i.e. they are type 83.

It is expected that in many cases this I-Beam functionality will be used in conjunction with 219 - Compress/Decompress vector of short integers. It would also be possible to encrypt the serialised form and write to a file (either component or native), and reverse the process at a later date.
$X$ is a scalar which can take the value 0 or 1 .
When $X$ is $1, Y$ can be any array. The result $R$ is the serialised form of the array, presented as a sint_vector.

When X is $0, \mathrm{Y}$ must be a sint_vector. The result R is an array whose serialised form is represented by Y .

Typically it is not possible to construct a vector which can be deserialised; it is expected that the only source of a vector which can be deserialised is the result of using 1 (220I) to serialise an array.

The result of 1 (220I) will differ between interpreters of differing widths and editions, but the resulting vector can be deserialised in other interpreters, with the exception that, like arrays in component files, it may not be possible to deserialise an array which was serialised in a later interpreter

The following identity holds true:

$$
A \equiv O(220 I) \text { O(219I) 1(219I) 1(220I) A }
$$

## Example

```
a<'ab'
b+1(220I)a
    b
```

$-33-10850003139002000979800$
$c+0(2201) b$
$\mathrm{c} \equiv \mathrm{a}$
1

## Number of Threads <br> $R+1111$ I $Y$

Specifies how many threads are to be used for parallel execution.
If $Y$ has the value $\theta, R$ is the number of virtual processors in the machine.
Otherwise, Y is an integer that specifies the number of threads that are to be used henceforth for parallel execution. Prior to this call, the default number of threads is specified by the environment variable APL_MAX_THREADS. If this variable is not set, the default is the number of virtual processors that the machine is configured to have.
$R$ is the previous value.
To reset the number of threads to be the same as the number of virtual processors run:

$$
\} 1111 \mathrm{I} 1111 I \theta
$$

## Update Function Time Stamp <br> $\{R\}-X(1159 I) Y$

$Y$ is an array of function names in the same format as the right argument of $\square A T$. For further information, see.
$X$ is an array of function attributes in the same format as the output of DAT.
The shy result $R$ is a vector of numeric items, one per each specified function containing the following values:

| 0 | No change was made; the name is not that of a function, or the function <br> was locked |
| :---: | :--- |
| 1 | The time and user stamp were updated |

Note that the last item of the function time stamp must be set to 0 otherwise 1159 I will generate a DOMAIN ERROR. Additionally, the time stamp must be greater than 1970110000.

```
Example
    ]disp DAT'Christmas'
    [\begin{array}{lllllllllllll}{0}&{0}&{0}&{2013}&{3}&{1}&{11}&{14}&{58}&{0}&{0}&{0}&{\mathrm{ Richard}}\\{\hline}\end{array}]
        x*-DAT 'Christmas'
        x (1159I) 'Christmas'
        ]disp DAT'Christmas'
[\vec{0 [0}0
```

## Specify Workspace Available $\quad R+2002 I Y$

This function is identical to the system function DWA except that it provides the means to specify the amount of memory ${ }^{1}$ that is committed for the workspace rather than have it assigned by the internal algorithm. Committed memory is memory that is allocated to a specific process and thereby reduces the amount of memory available for other applications.

Like DWA, 2002I compacts the workspace so that it occupies the minimum number of bytes possible, adds an extra amount, and then de-commits all the remaining memory that it is currently using, allowing it to be allocated by the operating system for use by other applications.

The argument $Y$ is an integer which specifies the size, in bytes, of this extra amount.
The purpose of the extra amount is to reduce the likelihood that APL will immediately have to ask the operating system to re-commit memory that it has just de-committed, something that would have a deleterious effect on performance. At the same time, if the extra amount were to be excessively large, APL could starve other applications of memory which itself could reduce the effective performance of the system. Whereas DWA calculates the size of the extra amount using a simple internal algorithm, 2002I uses a value specified by the programmer.
$R$ is an integer which reports the size in bytes of the memory committed for the workspace, and is the sum of the minimum amount required by the workspace itself and the argument $Y$.

If the size of the committed workspace would be smaller than the minimum value (specified by 2000I) or larger than the maximum value (which defaults to MAXWS), a DOMAIN ERROR is signalled.

Note that this function does not change the size of the extra amount that will be applied subsequently by $\square W A$ or by an automatic compaction.

[^7]
## Data Binding

$R+\{X\} 2015$ I $Y$
Creates an object that may be used as a data source for WPF data binding. ${ }^{1}$
Data binding connects a Binding Target to a Binding Source. In WPF a Binding Target is a particular property of a user interface object; for example, the Text property of a TextBox object. A Binding Source is a Path to a value in a data object (which may contain other values). The value of the Binding Source determines the value of the Binding Target. If two-way binding is in place, a change in a user-interface component causes the bound data value to change accordingly. In the example of the TextBox, the value in the Binding Source changes as the user types into the TextBox.
$Y$ is a character vector containing one of the following:

- the name of a variable
- the name of a namespace containing one or more variables
- the name of a variable containing a vector of refs to namespaces, each of which contains one or more variables.

If the name specified by $Y$ doesn't exist or represents neither a variable nor a namespace, the function reports DOMA IN ERROR. Currently, no further validation of the structure and contents of $Y$ is performed, but nothing other than the examples described herein is supported.

If the optional left argument $X$ is given and $Y$ is a variable other than a ref, $X$ specifies the binding type for that variable. If $Y$ specifies one or more namespaces, $X$ specifies the names and binding types of each of the variables which are to be bound, contained in the namespaces specified by Y .

The structure of $X$ depends upon the structure of $Y$ and is discussed later in this topic.
If $X$ is omitted, all of the variables specified by $Y$ are bound with default binding types.

Here the term bind variable refers to any variable specified by $X$ and $Y$ to be bound, and the term binding type means the .NET data type to which the value of the bind variable is converted before it is passed to the .NET interface.

[^8]2015 I creates a Binding Source object R. This is a .NET object which contains Path $(\mathrm{s})$ to one or more bind variables. This object may then be assigned to a property of a WPF object or passed a s as a parameter to a WPF method that requires a Binding Source.

## Bind Variables and Bind Types

A bind variable should be of rank 2 or less. Higher rank arrays are not supported.
If not specified by $X$, the binding type of a bind variable is derived from its content at the time 2015I is executed. The binding type is then stored with the variable in the workspace. There is no mechanism to change a variable's binding type without erasing the variable and re-executing 2015I. If you change the type or rank of a bind variable while it is bound (for example from a variable to a namespace), the behaviour of the system is unpredictable.

The default binding type is derived as follow:
If the bind variable is a simple scalar number the default binding type is System. Object. At the point when the value of the variable is passed to the .NET interface this will be cast to a numeric type such as System. Int16, System.Int32, System.Int64, or System. Double, depending upon the internal representation of the data. The .NET property to which it is bound will typically only accept a single Type (for example System. Int32), so to avoid unpredictable behaviour, it is recommended that the left argument $X$ be used to specify the binding type for numeric data.

If the bind variable is a character scalar or vector, the default binding type is also System.Object, but at the point when the value of the variable is passed to the .NET interface it will always be passed as System. String, which is suitable for binding to any property that accepts a System. String, such as the Text property of a TextBox.

If the bind variable is a vector other than a simple character vector, such as a vector of character vectors, a simple numeric vector, or a vector of .NET objects, the bind type will be a collection. This is suitable for binding to any property that represents a collection (list) of items, for example the ItemsSource property of a ListBox.

If the bind variable is a matrix, the default binding type is System. Object. It is likely that in a future release a rank-2 array will be bound as a DataTable.

All the examples that follow assume DUSING $\leftarrow$ 'System '.

## Binding Single Variables

In this case, $Y$ specifies the name of a variable which is one of the following:

- character vector (or scalar)
- numeric scalar
- scalar .NET object (not currently supported)
- vector of character vectors
- numeric vector
- vector of .NET objects
- matrix (not currently supported)
$X$ (if specified) defines the binding type for the bind variable named by $Y$ and is a single .NET Type.

Note that in the following examples, the reason for expunging the name first is discussed in the section headed Rebinding a Variable.

## Binding a Character Vector

This example illustrates how to bind a variable which contains a character vector.

```
DEX'txtSource'
txtSource<HELLO WORLD'
bindsource<2015I'txtSource'
```

In this example, the binding type of the variable $t \times t$ Source will be System. String, suitable for binding to any property that accepts a String, such as the Text property of a TextBox.

## Binding a Numeric Scalar

This example illustrates how to bind a variable which contains a numeric scalar value.

```
DEX'sizeSource'
sizeSource\leftarrow36
bindSource\leftarrowInt32(2015I)'sizeSource'
```

In this example, the left argument Int 32 specifies that the binding type for the variable sizeSource is to be System. Int32. This means that whenever APL passes the value of sizeSource to the control, it will first be cast to an Int32. This makes it suitable, for example, for binding to the FontSize property of a TextBox.

A number of controls have a Value property which must be expressed as a System. Double. The next example shows how to create a Binding Source for such a variable.

```
DEX'valSource'
valSource*42
bindSource<Double(2015I)'valSource'
```

## Binding a Scalar .NET Object

This is not supported in the first release of Version 14.0. It is intended that it will be added in due course.

## Binding a Vector of Character Vectors

WPF data binding provides the means to bind controls that display lists of items, such as the ListBox, ListView, and TreeView controls, to collections of data. These controls are all based upon the ItemsControl class. To bind an ItemsControl to a collection object, you use its ItemsSource property.

This example illustrates how to bind a variable which contains a vector of character vectors.

```
OEX'itemsSource'
itemsSource\leftarrow'beer' 'wine' 'water'
bindsource+2015I'itemsSource'
```

In this example, the binding type of the variable $i$ tems Source will be System. Collection, suitable for binding to the ItemSource property of an ItemsControl.

## Binding a Numeric Vector

By default, a numeric vector is bound in the same way as a vector of character vectors, i.e. as a System. Collection, suitable for binding to the ItemSource property of an ItemsControl.

```
DEX'yearsSource'
yearsSource <2000+\imath20
bindSource<2015I'yearsSource'
```

In principle, a numeric vector may alternatively be bound to a WPF property that requires a 1 -dimensional numeric array, by specifying the appropriate data type (e.g. Int32, Double) for the array as the left argument. For example:

```
DEX'arraySource'
arraySource \(\leftarrow 4224\)
bindSource↔Int32 (2015I)'arraySource'
```

## Binding a Vector of .NET Objects

A vector of .NET objects is bound in the same way as a vector of character vectors, i.e. as a System. Collection, suitable for binding to the ItemSource property of an ItemsControl.
$\uparrow$ Easter

202152
2022424
2023416
202455
$\mathrm{dt} \leftarrow\{\mathrm{DNEW} \text { DateTime } \omega\}^{*}$ Easter bindSourceャ2015I'dt'

## Binding a Matrix

Currently, the system allows a bind variable to contain a matrix (simple or nested) but the default binding type is System. Object. This is unlikely to be of any use. It is intended that in a future release of Dyalog APL a matrix will be bound as a DataTable or similar.

## Rebinding a Variable

As mentioned earlier, when a variable is bound its binding type is stored with it in the workspace. If you subsequently attempt to rebind the variable there is no mechanism in place to alter the binding type. If the current binding type (whether specified by the left argument $X$, or by being the default) differs from the saved one, the function will generate a DOMAIN ERROR.

```
    num\leftarrow42
    bs\leftarrow2015I'num'
    bs\leftarrow'Int32'(2015I)'num'
DOMAIN ERROR: You cannot redefine the binding types
    bs\leftarrow'Int32'(2015I)'num'
    ^
```

In this example, perhaps the programmer realised after binding num (with a default binding type of System. Object) that the binding type should really be System. Int 32, and simply was trying to correct the error. To avoid this problem, it is recommended that you expunge the name before using it.

```
DEX 'num'
num*42
bs\leftarrow2015I'num'\rho (default) binding type System.Object
DEX 'num'
num<42
bs\leftarrowInt32(2015I)'num'
```

## Binding A Namespace

In this case, $Y$ specifies the name of a namespace that contains one or more variables. By default, each variable is bound using its default binding type as described above. Objects other than variables are ignored.

If it is required to specify the binding type of any of the variables, or if certain variables are to be excluded, the left argument is a 2 -column matrix. The first column contains the names of the variables to be bound, and the second column their binding types.

## Example

The following code snippet binds a namespace containing two variables named $t x t$ Source and sizeSource. In this case, the name of each variable may be specified as the Path for a WPF property that requires a String or an Int32. For example, if bindSource were assigned to the DataContext property of a TextBox, its Text property could be bound to $t x$ Source and its FontSize property to sizeSource.

```
src*\squareNS''
src.txtSource\leftarrow'Hello World'
src.sizeSource\leftarrow36
options\leftarrow2 2\rho'txtSource'String'sizeSource'Int32
bindSource<options(2015I)'src'
```

## Binding a Vector of Namespaces

In this case, $Y$ specifies the name of a variable that contains a vector of refs to namespaces. In this case, the result $R$ is of type Dyalog. Data.DataBoundCollectionHandler which is suitable for binding to a WPF property that requires an IEnumerable implementation, such as the ItemsSource property of the DataGrid.

Each namespace in $Y$ represents one of a collection of instances of an object, which exports a particular set of properties for binding purposes. For example, $Y$ could specify a wine database where each namespace represents a different wine, and each namespace contains the same set of variables that contain the name, price (and so forth) of each wine.

## Example

winelist- पNS" (oWines) $\mathrm{mc}^{\prime \prime}$
winelist.Name $\leftarrow$ Wines
winelist.Price $<0.01 \times 10000+$ ? ( $\rho$ Wines) 10000
bindSource 2015 I'winelist'

## Flush Session Caption <br> $R+2022$ I $Y$

Under Windows, the Session Caption displays information such as the name of the current workspace. The contents of the Caption can be modified: see Window Captions in the Installation and Configuration Guide for more details.

However, the Caption is updated only at the six-space prompt; calling DLOAD for example from within a function will not result in the Caption being updated at the end of the DLOAD.

This I-Beam causes the Session Caption to be updated (flushed) when called. Note that this I-Beam does not alter the contents of the Caption.

## Example

2022I0

## Close All Windows <br> $R+2023$ I $Y$

Under Windows the option, Windows -> Close All Windows allows the user to close all open Editor and Tracer Windows, but does not reset the State Indicator.

This I-Beam mimics this behaviour, thus allowing the user to write code which can close all windows before attempting to save the workspace; it is not possible to save a workspace if any editor or tracer windows are open.

Under UNIX, this is the only mechanism for closing all such windows.

## Example

2023I0

## Set Workspace Save Options $R+2400 \pm Y$

This function sets a flag in the workspace that determines what happens when it is saved. The flag itself is part of the workspace and is saved with it.

If the flag is set, all Trace, Stop and Monitor settings will be cleared whenever the workspace is saved, whether by ) SAVE, पSAVE or by File/Save from the Session menubar.

Y must be 1 (set the flag) or 0 (clear the flag).
The result $R$ is the previous value of the flag.
This function may be extended in the future and a left-argument may be added.

## Example

(2400I) 1
0
) SAVE
O Trace bits cleared.
3 Stop bits cleared.
O Monitor bits cleared.
temp saved Sat Apr 05 17:01:30 2014

## Expose Root Properties $R+2401$ I $Y$

This function is used to expose or hide Root Properties, Event and Methods.
If $Y$ is 1 , Root Properties, Events and Methods are exposed.
If Y is 0 , no further Root Properties, Events or Methods are exposed; however any that have already been exposed will remain so.

This functionality is available in Windows versions by selecting or unselecting the Expose Root Properties MenuItem in the Options Menu in the Session. Note that deselecting this MenuItem only affects future references to Root Properties, Events or Methods.

This function is the only mechanism available under non-Windows versions of Dyalog APL; the state of this setting is saved in the workspace, and therefore cannot be controlled by an environment variable.

## Example

```
    #.GetEnvironment'MAXWS'
VALUE ERROR
        #.GetEnvironment'MAXWS'
        ^
    2401I1
0
64M #.GetEnvironment'MAXWS'
64M
    2401I0
1
    #.GetEnvironment'MAXWS'
64M
        #.GetCommandLine
VALUE ERROR
        #.GetCommandLine
    ^
```

## Close All Windows

$R+2023$ I $Y$

Under Windows the option, Windows -> Close All Windows allows the user to close all open Editor and Tracer Windows, but does not reset the State Indicator.

This I-Beam mimics this behaviour, thus allowing the user to write code which can close all windows before attempting to save the workspace; it is not possible to save a workspace if any editor or tracer windows are open.

Under UNIX, this is the only mechanism for closing all such windows.

## Example

2023I0

## Applies To: Session

## Description

If enabled, this event is reported when a value is about to be displayed in the Session. It is generated by the display of a variable or the result of a function including system variables and functions. Error messages and output from system commands do not generate this event.

The event message reported as the result of $\bar{D} Q$, or supplied as the right argument to your callback function, is a 2 -element vector as follows :

| $[1]$ | Object | ref or character vector |
| :--- | :--- | :--- |
| $[2]$ | Event | 'SessionPrint' or |

The attachment of a callback function intercepts and annuls the normal display of any value.

Note that this event may be extended in future; in particular the number of elements in the event message may be increased, and the event may be generated by some system commands. You should therefore allow for such extensions in any code which refers to SessionPrint.

When the event is generated, the left argument of the callback function contains the value which was about to be displayed. The callback function may display this or any other value, using default output or by assignment to $\square$. If so, this output will be processed normally, without generating a subsequent SessionPrint event. If the callback fails to explicitly display anything, nothing will appear in the Session.

## Example

DVR'DSE.TimeStamp'
$\nabla$ VAL TimeStamp EV
OTS VAL
$\nabla$
'DSE'DWS'Event' 'SessionPrint' 'DSE.TimeStamp'
2
20149181620383182
—A
2014918162044668 ABCDEFGHIJKLMNOPQRSTUVWXYZ

The result (if any) of the callback function is ignored.
You may not disable the event (by setting its action to ${ }^{-}$1), nor generate the event using $\square N Q$, nor call it as a method.

## Chapter 7:

## Object Reference Changes

## Error Messages when setting GUI Properties

The message displayed to indicate an error in the right argument to IWC, IWS and ZNEW has been improved.

The following statement may be deemed incorrect for two reasons.

$$
\text { 'F'DWC'Form' ('Posn' } 10 \text { 10)('TheCaption' 'andys') }
$$

- the second property specification ('TheCaption' 'andys') is malformed because there is no such property as 'TheCaption'.
- In the absence of a valid property name/value pair, the system expects a value for the Size property because Size comes after Posn in the list of Properties that apply to a Form, and a vector of character vectors is an invalid value for Size.

Previously, APL assumed the second case and displayed the error message:

```
RANK ERROR: There was an error processing the "Size" prop
erty
    'F'DWC'Form'('Posn' 10 10)('TheCaption' 'andys')
    ^
```

This was confusing because the statement contains no mention of the Size property.
The system will now generate the following error:

```
RANK ERROR: There was an error processing the property at
position 2 of the right argument
    'F'DWC'Form'('Posn' 10 10)('TheCaption' 'andys')
```

## CursorObj new style

The CursorObj Property has been extended; setting the Property to a value of 14 specifies the (Pointing) Hand cursor.

## Redraw Property

The Redraw Property has been extended; setting the Property to a value of 3 causes the object and all of its children to be redrawn immediately. As in previous versions of Dyalog APL, a value of 2 causes the object to be redrawn immediately, but not its children.

## DragDrop Event

The DragDrop Event used to always report the name of the dragged object in the event message regardless of the syntax used to specify the callback function.

Henceforth, if the callback function is specified using the onDragDrop syntax, the $3^{\text {rd }}$ element of the event message is a ref to the dragged object rather than its name. If you use the Event property to establish the callback, the $3^{\text {rd }}$ element of the event message is the name of the object as before.

This change makes the DragDrop event consistent with other events in the way that objects are reported in the event message.

## Chapter 8:

## Windows Presentation Foundation

## Introduction

Windows Presentation Foundation is a graphical system that includes a programmable Graphical User Interface. It is supplied as a set of Microsoft .NET assemblies and is supported on all current Windows platforms.

The WPF GUI is in many ways more sophisticated and powerful than either Dyalog APL's own built-in GUI or the GUI provided by Windows Forms.

Like any other set of .NET classes, WFP can be integrated into Dyalog APL applications via the .NET interface. Dyalog APL users may therefore develop GUI applications that are based upon WPF as an alternative to the built-in Dyalog GUI or Windows Forms.

Quite apart from its advanced GUI capabilities, WPF supports data binding. This is a complex subject, but putting it very simply, data binding allows a property of a userinterface object (such as the Text property of a TextBox object) to be bound to some data. When the data changes, the bound property of the object changes and vice versa.

Dyalog APL Version 14 includes a data binding function (2015 ${ }^{1}$ ) which supports data binding to APL arrays and namespaces.

A WPF GUI can be built dynamically by creating a set of component objects (using DNEW) in a similar way to the Dyalog APL GUI and Windows Forms. However, the same user-interface can instead be specified statically using XAML, a text markup system that describes the GUI using XML. Along with data binding, this feature allows the application logic and the user-interface to be developed and maintained separately.

The examples described in this section are provided in the workspace WPFINtro.dws

[^9]
## Temperature Converter Tutorial

This tutorial illustrates how to go about developing a simple WPF application in Dyalog APL. It is functionally identical to the GUI tutorial example that illustrates how to develop a GUI application using the built-in Dyaog APL Grahical user Interface. See Interface Guide: GUI Tutorial.

Like the GUI Tutorial, this is necessarily an elementary example, but illustrates the principles that are involved. The example is a simple Temperature Converter.

The user may enter a temperature value in either Fahrenheit or Centigrade and have it converted to the other scale.

No attempt has been made to update the WPF example, in terms of its user-interface, from the original version which was developed for Windows 3 . This allows a direct comparison to be made between using the WPF and using the built-in Dyalog GUI.

There are two versions provided. The first uses XAML to describe the user-interface with code to drive it. The second version is written entirely in APL code. The two versions of this example may be found in WPFINtro. dws in the namespaces UsingXAML and UsingCode respectively.

## Using XAML

The functions and data for this example are provided in the workspace WPFINtro. dws in the namespace WPF.UsingXAML. To run the example:

```
)LOAD WPFIntro
WPF.UsingXAML.TempConverter
```

Arguably the easiest way to create a WPF GUI is to define it using XAML. The XAML defines the structure, layout and appearance of the user-interface in a very concise manner. It is still necessary to write code to display the XAML and to respond to user actions, but the amount of code involved is minimal.

## The XAML for the Temperature Converter is shown below.

```
<Window
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Name="Temp"
    Title="WPF Temperature Converter"
    SizeToContent="WidthandHeight">
    <DockPanel LastChildFill="False">
            <Menu DockPanel.Dock="Top">
                    <MenuItem Header="_Scale">
                    <MenuItem Name="mnuFahrenheit" Header=" Fahrenheit"
                                    IsCheckable="True" IsChecked="True"/>
                            <MenuItem Name="mnuCentigrade" Header="_Centigrade"
                                IsCheckable="True"/>
                    </MenuItem>
            </Menu>
            <Grid Width="230" Margin="40,10,10,10">
                    <Grid.RowDefinitions>
                    <RowDefinition Height="Auto"/>
                    <RowDefinition Height="Auto"/>
                    <RowDefinition Height="Auto"/>
                    </Grid.RowDefinitions>
                    <Grid.ColumnDefinitions>
                    <ColumnDefinition Width="Auto"/>
                    <ColumnDefinition Width="80"/>
                    <ColumnDefinition Width="60"/>
            </Grid.ColumnDefinitions>
            <Label Grid.Row="0" Grid.Column="0" Content="Fahrenheit"/>
            <Label Grid.Row="1" Grid.Column="0" Content="Centigrade"/>
            <TextBox Name="txtFahrenheit" Grid.Row="0" Grid.Column="1"
                Margin="5"/>
            <TextBox Name="txtCentigrade" Grid.Row="1" Grid.Column="1"
                Margin="5"/>
            <Button Name="btnF2C" Grid.Row="0" Grid.Column="2"
                Content="F>C" Margin="5"/>
            <Button Name="btnC2F" Grid.Row="1" Grid.Column="2"
                Content="C>F" Margin="5"/>
            <Button Name="btnQuit" Grid.Row="2" Grid.Column="1"
                Content="Quit" Margin="5"/>
            </Grid>
            <ScrollBar Name="scrTemp" DockPanel.Dock="Right" Width="20"
                Orientation="Vertical" Minimum="1" Maximum="213">
            </ScrollBar>
        </DockPanel>
</Window>
```

The window defined by this XAML is illustrated in the screen image shown above. Let us examine the XAML, component by component.

## Parent and Child Controls

First, notice how the structure of the GUI is defined by enclosing the child components inside the opening and closing tags of its parent. So:

```
<Window
    ...
    <DockPanel>
...
    </DockPanel>
</Window>
```

specifies a Window control that contains a DockPanel control.
Similarly,

<Menu>
<MenuItem ... >
<MenuItem ... />
<MenuItem ... />
</MenuItem>
</Menu>
defines a Menu that contains a MenuItem, that itself contains two other MenuItem objects.

## Named and Un-named Controls

Secondly, notice that certain objects are named whereas others are not. For example: TextBox Name="mnuFahrenheit defines a TextBox namedtxtFahenheit; whereas <Dockpanel . . .> defines an unnamed DockPanel object.

Objects are given names so that they can be referenced from the code that displays content in the user-interface or handles the user actions. In this case, the code will read the content of the txtFahrenheit TextBox but has no need to reference the DockPanel.

## The Main Window

```
<Window
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Name="Temp"
    Title="WPF Temperature Converter"
    SizeToContent="WidthandHeight">
...
</Window>
```

This extract of XAML defines a Window control; a top-level window that is equivalent to a Dyalog APL GUI Form.

The $x m \ln s$ attributes define the XML namespaces (effectively the vocabulary of the xml scheme) and are mandatory in an XAML document.

The name of the TextBox is Temp, and its caption is WFP Temperature Converter. The SizeToContent property is set to "WidthandHeight", which causes the TextBox to automatically size itself to fit its content in both horizontal and vertical directions.

## The DockPanel

```
<DockPanel LastChildFill="False">
</DockPanel>
```

WPF provides a number of layout controls. These are containers whose only purpose is to arrange child controls in a particular way, and to dictate how they are rearranged when the parent window is resized. The DockPanel is one of the simplest of the WPF layout controls.

In this case, the DockPanel is controlling 3 child windows a Menu, a Grid and a ScrollBar.

The attachment of a particular child control is specified by setting its DockPanel. Dock property. By default, the last control added to a DockPanel is stretched to fill the remaining space when the window is expanded. In this case, the requirement is for a fixed-width scrollbar attached to the right edge, so the default is overriden by setting the LastChildFill property to "False".

## The Menu

```
<Menu DockPanel.Dock="Top">
    <MenuItem Header="_Scale">
            <MenuItem Name="mnuFahrenheit" Header=" Fahrenheit"
                IsCheckable="True" IsChecked="True"/>
            <MenuItem Name="mnuCentigrade" Header="_Centigrade"
                IsCheckable="True"/>
    </MenuItem>
</Menu>
```

The above extract from the XAML defines a Menu. Setting Dock to "Top" causes the Menu as a whole to be docked, so that it appears like a menubar, along the top of the DockPanel. The Menu contains a single MenuItem labelled Scale which itself contains two sub-items labelled Fahrenheit and Centigrade respectively. The IsCheckable property specifies whether or not the user can check the MenuItem, and the IsChecked property sets and reports its checked state. The underscore characters (e.g. as in "_Scale") identify the following character as a keyboard shortcut.

## The Grid

```
<Grid Width="230" Margin="40,10,10,10">
</Grid>
```

The Grid object is another WPF layout control that organises other controls in rows and columns. Here, the XAML defines a Grid with a width of 230; a left margin if 40 , and a top, right and bottom margin of 10 . As there is no explicit unit specified, the system uses the default device-independent unit ( $p x$ ) of $1 / 96^{\text {th }}$ inch.

The rows and columns of a Grid are defined by collections of RowDefinition and ColumnDefinition objects.

Here the XAML specifies that the Grid contains 3 rows, each of which has a Height set to "Auto" which means that its height depends upon the height of its content.

```
<Grid.RowDefinitions>
    <RowDefinition Height="Auto"/>
    <RowDefinition Height="Auto"/>
    <RowDefinition Height="Auto"/>
</Grid.RowDefinitions>
```

Similarly, there are 3 columns. The first column (which will contain labels) takes its width from its content, i.e. it will be just wide enough to display the longest label. The other columns for the edit boxes and buttons are specified to be 80 px and 60 px wide respectively. In this case, the content (TextBox and Button objects) will take their widths from that of the column.

```
<Grid.ColumnDefinitions>
    <ColumnDefinition Width="Auto"/>
    <ColumnDefinition Width="80"/>
    <ColumnDefinition Width="60"/>
</Grid.ColumnDefinitions>
```

## The Label Objects(Column 1)

```
<Label Grid.Row="0" Grid.Column="0" Content="Fahrenheit"/>
<Label Grid.Row="1" Grid.Column="0" Content="Centigrade"/>
```

Here the XAML specifies Label objects Fahrenheit and Centigrade. Because they are defined within the <Grid> . . </Grid> tags, they are child objects of the Grid. In addition it is necessary to specify in which cells they are displayed using their Grid. Row and Grid. Column properties. Note that the cell coordinates have zero origin.

## The TextBox Objects(Column 2)

```
<TextBox Name="txtFahrenheit" Grid.Row="0" Grid.Column="1"
    Margin="5"/>
<TextBox Name="txtCentigrade" Grid.Row="1" Grid.Column="1"
    Margin="5"/>
```

The XAML specifies two TextBox objects named txtFahrenheit and txtCentigrade respectively. Setting Marg in to " 5 " means that a margin of 5 px is applied around each edge; otherwise the text boxes would occupy the entire width of the column $(80 \mathrm{px})$. The effective width of each TextBox will therefore be $70 \mathrm{px}(80-2 \times 5)$.

## The Button Objects (Column 3)

```
<Button Name="btnF2C" Grid.Row="0" Grid.Column="2"
    Content="F>C" Margin="5"/>
<Button Name="btnC2F" Grid.Row="1" Grid.Column="2"
    Content="C>F" Margin="5"/>
<Button Name="btnQuit" Grid.Row="2" Grid.Column="1"
    Content="Quit" Margin="5"/>
```

The XAML specifies three named Button controls. Note that the caption on a Button is specified by its Content property.

## The ScrollBar Object

This example uses a ScrollBar which the user may scroll to input a value, either in Fahrenheit or Centigrade depending upon which of the two menu items (Fahrenheit or Centigrade) is checked. ${ }^{1}$

```
<ScrollBar Name="scrTemp" DockPanel.Dock="Right" Width="20"
    Orientation="Vertical" Minimum="1" Maximum="213">
</ScrollBar>
```

This XAML snippet defines a ScrollBar named scrTemp.
Setting DockPanel. Dock to "Right" means that it will be docked (aligned) on the right edge of the DockPanel. It will be a vertical scrollbar, have a fixed width of 20 px and a default height. The range of the ScrollBar is defined by its Minimum and Maximum properties which are set so that the ScrollBar will specify a value in Fahrenheit.

Note that in order to cause the ScrollBar to be docked (aligned) along the right edge of the DockPanel it is necessary to set LastChildFill to "False" (for the DockPanel) and Dock to "Right" (for the ScrollBar), because the value of LastChildFill (default "True") overrides the Dock value of the last defined child of the DockPanel.

## Note

The XAML that defines this user-interface is at the same time both simple and complex. It is simple because (in this case) it is readily understood. It is complex because in order to write it, the user-interface designer must understand precisely how the various controls and their properties behave and work together. For these details, you should refer to the appropriate documentation and check out the large number of examples published on the internet.

[^10]
## The Code to display the XAML

The function TempConverter shown below contains the code needed to display and operate the user interface whose layout is defined by the XAML described above.

```
\nabla TempConverter;str;xml;win;txtFahrenheit;txtCentigrade;
    mnuFahrenheit;mnuCentigrade;btnF2C;
    btnC2F;btnQuit;scrTemp;sink
[1] ZUSING+'System'
[2] DUSING,+c'System.IO'
[3] DUSING,*c'System.Windows.Markup'
[4] UUSING,*c'System.Xml,system.xml.dll'
[5] ZUSING,+c'System.Windows.Controls.Primitives,
    WPF/PresentationFramework.dll'
[6]
[7] str&DNEW StringReader(cXAML)
[8] xml*-DNEW XmlTextReader str
[9] win+XamlReader.Load xml
[10]
[11] txtFahrenheit+win.FindNamec'txtFahrenheit'
[12] txtCentigrade\leftarrowwin.FindNamec'txtCentigrade'
[13] mnuFahrenheit+win.FindNamec'mnuFahrenheit'
[14] mnuFahrenheit.onClick<'SET_F'
[15] mnuCentigrade+win.FindNamec'mnuCentigrade'
[16] mnuCentigrade.onClick+'SET_C'
[17] (btnF2C\leftarrowwin.FindNamec'btnF2C').onClick<'f2c'
[18] (btnC2F*win.FindNamec'btnC2F').onClick*'c2f'
[19] (btnQuit+win.FindNamec'btnQuit').onClick+'Quit'
[20] (scrTemp<win.FindNamec'scrTemp').onScroll<'F2C'
[21] sink*win.ShowDialog
\nabla
```

The variable XAML (a character vector) contains the XAML described previously.
Note that apart from the names given to the objects by the XAML and used by the function, the XAML and the code are independent.

TempConverter[7-8] create an XamlReader object from the character vector via StringReader and XmlTextReader objects.

```
[8] xml-DNEW XmlTextReader str
```

TempConverter[9] instantiates the XAML content by calling its Load method, which returns a reference win to the top-level control (in this case a Window) defined therein. The Window is not yet visible.

```
win<XamlReader.Load xml
```

Earlier, it was explained that objects defined bt the XAML must be named in order that they can be referenced (used) by the code. The mechanism to achieve this is to call the FindName method of the Window, which returns a reference to the specified (named) object. So these statements:

```
[11] txtFahrenheit*win.FindNamec'txtFahrenheit'
[12] txtCentigrade*win.FindNamec'txtCentigrade'
```

obtain refs (in this case named $t x t F$ ahrenheit and $t x t$ Centigrade) to objects named $t x t$ Fahrenheit and $t x t$ Centigrade. It is convenient (but not essential) to use the same name for the ref as is used for the control.

Most of the remaining statements obtain refs to the MenuItem, Button and ScrollBar objects and attach callback functions to their Click and Scroll events respectively.

```
[13] mnuFahrenheit+win.FindNamec'mnuFahrenheit'
[14] mnuFahrenheit.onClick\leftarrow'SET_F'
[15] mnuCentigrade\leftarrowwin.FindNamec'mnuCentigrade'
[16] mnuCentigrade.onClick<'SET_C'
[17] (btnF2C\leftarrowwin.FindNamec'btnF2C').onClick<'f2c'
[18] (btnC2F*win.FindNamec'btnC2F').onClick+'c2f'
[19] (btnQuit<win.FindNamec'btnQuit').onClick<'Quit'
[20] (scrTemp\leftarrowwin.FindNamec'scrTemp').onScroll*'F2C'
```

Finally the code displays the Window and hands it over to the user by calling the ShowDialog method of the top-level Window.
[21] sinkヶwin.ShowDialog
ShowDialog displays the Window modally; i.e. until it is closed, the user may interact only with that Window. It is equivalent to DDQ win or win. Wait in the Dyalog built-in GUI.

## The CallBack Functions

The callback functions are named as they are in the basic Dyalog GUI example and are remarkably similar. See Interface Guide: GUI Tutorial.
Callback function f 2 c which is attached to the Click event of the btnF2C button (labelled $F>C$ ) reads the character string in the tx tF ahrenheit TextBox, converts it to a number using Text 2 Num, calculates the equivalent in centigrade and then displays the result in the txtCentigrade TextBox.

```
\nabla f2c;value
[1] A Callback to convert Fahrenheit to Centigrade
[2] :If 1=\rho,value\leftarrowText2Num txtFahrenheit.Text
[3] txtCentigrade.Text<2\Phi(value-32) }\times5\div
[5] txtCentigrade.Text<'invalid'
    :EndIf
    \nabla
```

[4] :Else

For completeness, the Text2Num function is shown below. Note that if the user enters an invalid number, Text2Num returns an an empty vector, and the callback displays the text invalid instead.

```
[1]
    \nabla num\leftarrowText2Num txt;val
    val num-\squareVFI txt
[2] num*val/num
    \nabla
```

The c 2 f function converts from Centigrade to Fahrenheit when the user presses the button labelled $C>F$.

```
\nabla c2f;value
[1] ค Callback to convert Centigrade to Fahrenheit
[2] :If 1=\rho,value\leftarrowText2Num txtCentigrade.Text
[3] txtFahrenheit.Text<2\Phi32+value }\div5\div
        txtFahrenheit.Text*'invalid'
        :EndIf
    \nabla
```

[4] :Else

The callbacks F2C and C2F, one of which at a time is attached to the Scroll event of the ScrollBar object are shown below. The argument Msg contains two items, namely:

| $[1]$ | Object | a ref to the ScrollBar object |
| :--- | :--- | :--- |
| $[2]$ | Object | a ref to an object of type <br> System.Windows.Controls.Primitives.ScrollEventArgs |

In this case the code uses the NewValue property of the ScrollEventArgs object. An alternative would be to refer to the Value property of the ScrollBar object
$\nabla$ F2C Msg; C;F; val
[1] $\quad$ Callback for Fahrenheit input via scrollbar
[2] txtFahrenheit.Text $+2 \Phi$ val $+213-(2 د M s g)$. NewValue
[3] txtCentigrade.Text $+2 \Phi(v a l-32) \times 5 \div 9$
$\nabla$

```
\nabla C2F Msg;C;F;val
[1] A Callback for Centigrade input via scrollbar
[2] txtCentigrade.Text<2कval\leftarrow101-(2دMsg).NewValue
[3] txtFahrenheit.Text<2ゅ32+val \div5\div9
    \nabla
```

The callbacks SET_F and SET_C which are attached to the Click events of the two MenuItem objects are shown below.

```
    \nabla SET_F
[1] A Sets the scrollbar to work in Fahrenheit
[2] scrTemp.(Minimum Maximum)\leftarrow1 213
[3] scrTemp.onScroll*'F2C'
[4] mnuFahrenheit.IsChecked<1
[5] mnuCentigrade.IsChecked}<
    \nabla
    \nabla SET_C
[1] }\quad~\mathrm{ Sets the scrollbar to work in Centigrade
[2] scrTemp.(Minimum Maximum)\leftarrow1 101
[3] scrTemp.onScroll ''C2F'
[4] mnuCentigrade.IsChecked<1
[5] mnuFahrenheit.IsChecked\leftarrow0
\nabla
```

Finally, the callback function Quit which is attached to the Click event on the Quit button, simply calls the Close method of the Window:

```
    \nabla Quit arg
        win.Close
    \nabla
```

Notice that unlike its equivalent in the Dyalog GUI, it is not appropriate to close the Window using the expression $\square E X$ 'win'. This would expunge the ref to the Window but have no effect on the Window itself.

## Using Code

The functions for this example are provided in the workspace WPFINtro. dws in the namespace WPF. Us ingCode. To run the example:

```
)LOAD WPFINtro
WPF.UsingCode.TempConverter
```

The following function TempConverter performs exactly the same task of defining and manipulating the user-interface for the Temperature Converter example using XAML which was discussed previously.

The callback functions it uses are identical.

```
\nabla TempConverter;QUSING;win;dp;mnu;mnuFahrenheit;
            mnuCentigrade;gr;tn;rd1;rd2;rd3;
                        rc1;rc2;rc3;l1;l2;txtFahrenheit;
                        txtCentigrade;btnF2C;btnC2F;
                        btnQuit;sink;mnuScale;scrTemp

[115] dp.SetDock scrTemp Dock.Right
[116]
[117] win.Content+dp
[118]
[119] sink\leftarrowwin.ShowDialog
    \nabla
```

Although this approach appears at first sight to be considerably more verbose than using XAML (a 120 -line function compared with a 21 -line function and a 44 -line block of XAML) each line of code performs only one very simple task, and no attempt has been made to write utility functions to perform the same task for similar controls, as might be done in a real application.

As before, let us examine the code line-by-line.
TempConverter[2-5] define DUSING so that the appropriate .NET assemplies are on the search-path. Note that the ScrollBar control is in System.Windows.Controls.Primitives and not System.Windows.Controls like the others.

```
[2] [USING\leftarrow,c'System.Windows.Controls,
    WPF/PresentationFramework.dll'
[3] DUSING,&'System.Windows.Controls.Primitives,
        WPF/PresentationFramework.dll'
[4] DUSING,*'System.Windows,
    WPF/PresentationFramework.dll'
[5] DUSING,*C'System.Windows,
    WPF/PresentationCore.dll
```

TempConverter[8-9] creates a Window and sets its SizeToContent and Title properties as in the XAML example. Notice however that whereas using XAML the string SizeToContent="WidthandHeight" is sufficient, when using code it is necessary to get theType right. In this case, the SizeToContent property must be set to a specific member (in this case WidthAndHeight) of the System. Windows.SizeToContent enumeration. Other members of this Type are Width, Height and Manual (the default).

```
[7] win*-DNEW Window
[8] win.SizeToContent+SizeToContent.WidthAndHeight
[9] win.Title\leftarrow'WPF Temperature Converter'
```

TempConverter[11-12] create a DockPanel control ansd set its LastChildFill property to 0 . In this case the APL value 0 is used instead of the string "False" in XAML.
[11] dp-पNEW DockPanel
[12] dp.LastChildFill +0
TempConverter[14] creates a Menu control.
[14] mnu- $\square$ NEW Menu

TempConverter[16-18] create a MenuItem control with the caption Scale, and then add the control to the Items collection of the main Menu using its Add method. This illustrates one significant difference between using XAML and code. In XAML, the parent/child relationships between controls are defined by the structure and order of the XML. Using code, child controls must be explicitly added to the appropriate list of child controls managed by the parent.

```
[16] mnuScale<\squareNEW MenuItem
[17] mnuScale.Header*'_Scale'
[18] sink&mnu.Items.Ad\overline{d mnuScale}
```

TempConverter[20-25] create a MenuItem control labelled Fahrenheit.The IsCheckable and IsChecked properties are set to 1 , which is equivalent to "True" in XAML. The callback function SET_F is assigned to the Click event exactly as in the XAML version of this example. The last line in this section makes the Fahrenheit MenuItem a child of the Scale Menu I tem.

```
[20] mnuFahrenheit<पNEW MenuItem
[21] mnuFahrenheit.Header*'Fahrenheit'
[22] mnuFahrenheit.IsCheckable<1
[23] mnuFahrenheit.IsChecked+1
[24] mnuFahrenheit.onClick\leftarrow'SET_F'
[25] sink\leftarrowmnuScale.Items.Add mnüFahrenheit
```

The code used to create the Centigrade MenuItem is more or less the same.
TempConverter[34-35] adds the top-level Menu to the DockPanel. Note that in the case of a DockPanel, the list of its child controls is represented by its Children property. Furthermore, to define how it is docked this is done, using code, by the SetDock method of the DockPanel. This contrasts with the way this is achieved using XAML (DockPanel. Dock="Top"). Note too that the argument to SetDock is not just a simple string as in XAML, but a member of the System.Windows.Controls. Dock enumeration.
[34] sink+dp.Children.Add mnu
[35] dp.SetDock mnu Dock.Top
TempConverter[37-39] create the Grid control. Its Width property will accept a simple numeric value, but its Marg in property must be given an instance of a System. Windows. Thickness structure. In this case, the ThickNess constructor is given a 4 -element numeric vector that specifies its Left, Top, Right and Bottom members respectively.

| [37] | gr*-DNEW Grid |  |
| :---: | :---: | :---: |
| [38] | gr.Width $\leftarrow 230$ |  |
| [39] | gr.Margin $-\square N E W$ | Thickness(40 1010 10) |

TempConverter[41-47] create instances of 3 RowDefinition classes and add them to the RowDefinitions collection of the Grid. Note that whereas in XAML the Height can be specified as a string, using code it is necessary once again to use the correct Type. In this case, Height must be specified by a member of the System. Windows. GridLength structure.

```
[41] rd1+\squareNEW RowDefinition
[42] rd1.Height*GridLength.Auto
[43] rd2&पNEW RowDefinition
[44] rd2.Height*GridLength.Auto
[45] rd3*DNEW RowDefinition
[46] rd3.Height+GridLength.Auto
[47] gr.RowDefinitions.Add"rd1 rd2 rd3
```

Similarly, TempConverter[49-55] create instances of 3 ColumnDefinition classes and add them to the ColumnDefinitions collection of the Grid. Note that The Width property will not accept a simple numeric value, it must be a member of the GridLength structure. To set the Width to 80 , it is necessary first to create an instance of a GridLength structure giving this value as the argument to its constructor.

| [49] | rci- ${ }^{\text {a }}$ NEW ColumnDefinition |
| :---: | :---: |
| [50] | rci.Width + GridLength. Auto |
| [51] | rc2- CNEW ColumnDefinition |
| [52] | rc2. Width--DNEW GridLength 80 |
| [53] | rc3- CNEW ColumnDefinition |
| [54] | rc3.Width- ${ }^{\text {dNEW }}$ GridLength 60 |
| [55] | gr.ColumnDefinitions.Add"rc1 rc2 rc |

## TempConverter[57-61] create a Label control with the caption Fahrenheit.

 To display the Label in a Grid it is necessary to first add it to the Children collection of the Grid, and then set its position in the Grid using its SetRow and SetColumn methods. Similar code is used to create and position the second Label.```
[57] l1-पNEW Label
[58] l1.Content<'Fahrenheit'
[59] sink*gr.Children.Add l1
[60] gr.SetRow l1 0
[61] gr.SetColumn l1 0
```

TempConverter[69-73] create and position a TextBox control, in the same way as the Label controls. Notice that in this case, the constructor for the Thickness structure is given a single value that specifies all four of its Left, Top, Right and Bottom members.
[69] txtFahrenheit - पNEW TextBox
[70] txtFahrenheit.Margin - DNEW Thickness 5
[71] sink\&gr.Children.Add txtFahrenheit
[72] gr.SetRow txtFahrenheit 0
[73] gr.SetColumn txtFahrenheit 1
TempConverter[81-87] create and position a Button control. The callback function f 2 c is attached to the Click event in the same way as in the XAML version of this example.

```
[81] btnF2C&\squareNEW Button
[82] btnF2C.Content <'F>C'
[83] btnF2C.Margin< पNEW Thickness 5
[84] btnF2C.onClick*'f2c'
[85] sink&gr.Children.Add btnF2C
[86] gr.SetRow btnF2C 0
[87] gr.SetColumn btnF2C 2
```

TempConverter [105] adds the Grid to the list of Children to be managed by the DockControl.

```
[105] sink \(+d p . C h i l d r e n . A d d ~ g r ~\)
```

TempConverter[107-112] create a ScrollBar control. Its Width, Minimum and Maximum properties all accept simple numeric values. However, its Orientation property must be set to a member of the System.Windows.Controls.Orientation enumeration.

```
[107] scrTemp+\squareNEW ScrollBar
[108] scrTemp.Width+20
[109] scrTemp.Orientation*Orientation.Vertical
[110] scrTemp.Minimum&1
[111] scrTemp.Maximum }+21
[112] scrTemp.onScroll*'F2C'
```

TempConverter[114-115] add the ScrollBar to the list of Children managed by the DockPanel, and use its SetDock method to cause it to be rightaligned.
[114] sink+dp.Children.Add scrTemp
[115] dp.SetDock scrTemp Dock.Right

Finally, the DockPanel is assigned to the Content property of the Window, and the Window displayed as in the XAML version of this example. Note that a Window may contain just one control.
[117] win.Content+dp
[118]
[119] sink↔win.ShowDialog

## Data Binding

This section provides some simple examples of WPF data binding using Dyalog APL. Each example builds upon the one before, so it is advisable to read them in order.

## Example 1

This example illustrates data binding using XAML to specify the user-interface coupled with an APL function to drive it and handle the data binding.

## The XAML

The XAML shown below, describes a Window containing a TextBox.

```
<Window
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Name="Temp"
    Title="Data Binding (Text)"
    SizeToContent="WidthandHeight">
        <TextBox Name="txt" Width="300" Margin="5"
        Text="{Binding txtSource,Mode=TwoWay,
            UpdateSourceTrigger=PropertyChanged} "/>
</Window>
```

It contains a data binding expressions, namely:

```
Text="{Binding txtSource,Mode=TwoWay,
    UpdateSourceTrigger=PropertyChanged} "
```

This specifies that the Text property of the TextBox is bound to a value in the Binding Source (which has yet to be defined) whose path is txtSource. The binding mode is set to TwoWay which means that any change in the TextBox will be reflected in a new value in the Binding Source, and vice-versa. The value in the Binding Source will be updated when the property (in this case the Text Property) changes.

## The APL Code

The function Text which generates this example is shown below.
The argument $t x t$ is the text to be displayed initially in the TextBox. Note that the variable XAML_Text contains the XAML that describes the user-interface listed above.

```
\nabla Text txt;口USING;str;xml;win
    DUSING,*,c'System.Windows.Controls,
    WPF/PresentationFramework.dll'
[2] win<LoadXAML XAML_Text
[3] win.txtBox*win.FiñdNamec'txt'
[5] DEX'txtSource'
[6] txtSource\leftarrowtxt
[7] win.txtBox.DataContext<2015I'txtSource'
    win.Show
    \nabla
```

[4]
[8]
[9]

The utility function LoadXAML incorporates the 3 lines of code, used to create a WPF window from XAML, that were coded in-line in previous examples in this chapter.

```
    \nabla win<LoadXAML xaml;DUSING;str;xml
[1] UUSING*'System.IO'
[2] ZUSING,*C'System.Windows.Markup'
[3] UUSING,*C'System.Xml,system.xml.dll'
[4] DUSING,*C'System.Windows.Controls,
        WPF/PresentationFramework.dll'
    str-\squareNEW StringReader(cxaml)
    xml-\squareNEW XmlTextReader str
    win<XamlReader.Load xml
    \nabla
```

Text [1] defines the .NET search path needed to access the WPF controls.
[1] ZUSING,ヶ,c'System.Windows.Controls, WPF/PresentationFramework.dll'

Text[2-3] uses the utility function LoadXAML to load a WPF user-interface from the XAML and then uses the FindName method to obtain a reference to the object named $t x t$.

```
[2] win\leftarrowLoadXAML XAML
[3] win.txtBox*win.FindNamec'txt'
```

Text[5-6] initialise a new global variable named $t \times t$ Source to the value of the argument. When using a global variable as a data binding source, it is generally advisable to establish a new variable by first expunging it. ${ }^{1}$

## [5] Dex'txtSource' <br> [6] txtSource $\leftarrow$ txt

Text[7]creates a Binding Source object using 2015I and assigns it to the DataContext property of the TextBox object. Because it is a character vector, the exported Type for the bound variable $t \times t$ Source is System. String which is appropriate for the Text property of a TextBox.

## [7] win.txtBox.DataContext $+2015 I^{\prime t} t x t$ Source'

Text[9] displays the Window. Note that although the APL local variable win goes out of scope when the function terminates, the Window remains visible until the user has closed it.
[9] win.Show

## Testing the Data Binding

The following expressions may be used to explore the effect of data binding.

[^11]Typing into the TextBox changes the value of the bound variable.

This example illustrates the use of the optional left argument to 2015 I to specify the data type used to export the value of the bound variable.

## The XAML

The XAML shown below, describes the same Window containing a TextBox as before.

```
<Window
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Name="Temp"
    Title="Data Binding (FontSize)"
    SizeToContent="WidthandHeight">
        <TextBox Name="txt" Text="Hello World" Width="300"
        Margin="5"
        FontSize="{Binding sizeSource,Mode=OneWay}"/>
</Window>
```

This time, the data binding expression is:

```
FontSize="{Binding sizeSource,Mode=OneWay}"/>
```

This specifies that the FontSize property of the TextBox is bound to a value in the Binding Source (which has yet to be defined) whose path is sizeSource. The binding mode is set to OneWay which means that the FontSize property depends on the data value but not vice versa. Were the FontSize to change for any external reason (which is admittedly unlikely in the case of FontSize), it would not alter the value in sizeSource to which it is bound.

## The APL Code

The function FontSize is almost identical to the function Text which is described in Example 1.

```
\nabla FontSize size;口USING;win
[1] ZUSING<'System'
[2] DUSING,*C'System.Windows.Controls,
                                WPF/PresentationFramework.dll'
[3] win<LoadXAML XAML
[4] win.txtBox*win.FindNamec'txt'
[6] DEX'sizeSource'
[7] sizeSource*size
[8] win.txtBox.DataContext<Int32(2015I)'sizeSource'
[10] win.Show
\nabla
```

[5]
[9]

The key difference is in FontSize[8]. Here the left argument of (2015I) is Int 32. This means that the exported Type of the variable sizeSource will be Int32. This Type (a 32-bit integer) is required by the FontSize property of a TextBox; no other Type will do. If this were omitted, APL would export the value of the variable using a Type dependent on its internal format (most likely Int16) and the binding would fail.
[8] win.txtBox.DataContext世Int32(2015I)'sizeSource'

## Testing the Data Binding

) LOAD WPFIntro
)CS DataBinding.FontSize
FontSize 12

## Example 3

This example, uses APL code to both build the user-interface (instead of using XAML) and handle the data binding. In this case both the Text and the FontSize properties are bound to APL variables. The function is shown below:

```
    \nabla TextFontSize(txt size);DUSING;win;sink
    ZUSING*'System'
    ZUSING,\leftarrow,c'System.Windows.Controls,
        WPF/PresentationFramework.dll'
[3] DUSING,\leftarrow'System.Windows.Controls.Primitives,
            WPF/PresentationFramework.dll'
[4]
    ZUSING,*c'System.Windows,
        WPF/PresentationFramework.dll'
    ZUSING,«'System.Windows,
        WPF/PresentationCore.dll'
    a Create a Window, DockPanel and TextBox
        win<पNEW Window
        win.SizeToContent*SizeToContent.WidthAndHeight
[9]
        win.Title\leftarrow'Data Binding (Text and FontSize)'
        win.txtBox+\squareNEW TextBox
[11] win.txtBox.WeWth*350
[13] win.Content*win.txtBox
[14]
[15]
[16]
        A Define data binding from variable "txtSource"
        A to the Text property of TextBox win.txtBox
        DEX'txtSource'
        txtSource\leftarrowtxt
        win.txtbinding*-DNEW Data.Binding(c'txtSource')
[19]
[20] win.txtbinding.Source+2015I'txtSource'
[21] win.txtbinding.Mode }+\mathrm{ Data.BindingMode.TwoWay
[22] win.txtbinding.UpdateSourceTrigger*
            Data.UpdateSourceTrigger.PropertyChanged
[23]
    sink+win.txtBox.SetBinding
                            TextBox.TextProperty win.txtbinding
[24]
[25]
    a Define data binding from variable "sizeSource"
[26] \rho to the FontSize property of TextBox win.txtBox
[27] DEX'sizeSource'
[28] sizeSource*size
[29] win.fntbinding*-DNEW Data.Binding(c'sizeSource')
[30] win.fntbinding.Source\leftarrowInt32(2015I)'sizeSource'
[31] win.fntbinding.Mode+Data.BindingMode.OneWay
[32] sink+win.txtBox.SetBinding
                            TextBox.FontSizeProperty win.fntbinding
[33]
[34] win.Show
    \nabla
```

Apart from the code that creates the controls, the only material difference between this and the previous examples is the way that the bindings are handled.

In code (as opposed to using XAML) this is done using explicit Binding objects ${ }^{1}$ The code for binding the Text property to the $t \times t$ Source variable is as follows:

```
[19] win.txtbinding<्पNEW Data.Binding(c'txtSource')
[20] win.txtbinding.Source+2015I'txtSource'
[21] win.txtbinding.Mode }\leftarrow\mathrm{ Data.BindingMode.TwoWay
[22] win.txtbinding.UpdateSourceTrigger*
    Data.UpdateSourceTrigger.PropertyChanged
[23] sink+win.txtBox.SetBinding
    TextBox.TextProperty win.txtbinding
```

Line [19] creates a Binding object, passing the constructor the the name of the APL variable $t \times t$ Source as the Path to the binding value.

```
[19] win.txtbinding<-DNEW Data.Binding(c'txtSource')
```

Line [20] creates a Binding Source object using 2015I as before, but this time assigns it to the Source property of the Binding object.
[20] win.txtbinding.Source-2015I'txtSource'
Line [21] sets the Mode property of the Binding object to TwoWay (a field of the BindingMode Type). As in Example 1, this specifies two-way binding.
[21] win.txtbinding.Mode $\leftarrow$ Data.BindingMode.TwoWay
Line [22] sets the UpdateSourceTrigger property of the Binding object to PropertyChanged (a field of the UpdateSourceTrigger Type). This causes the value in the Binding Source (in this case $t \times t$ Source) to be changed whenever the property (in this case the Text property) of the TextBox changes. This will occur on every keystroke.
[22] win.txtbinding.UpdateSourceTrigger Data.UpdateSourceTrigger. PropertyChanged
(Note that the three types Binding, BindingMode and UpdateSourceTrigger are located in System.Windows. Data)

The code that establishes the binding between the sizeSource variable and the FontSize property is very similar.

[^12]```
[29] win.fntbinding--NNEW Data.Binding(c'sizeSource')
[30] win.fntbinding.Source<Int32(2015I)'sizeSource'
[31] win.fntbinding.Mode\leftarrowData.BindingMode.OneWay
[32] sink<win.txtBox.SetBinding
        TextBox.FontSizeProperty win.fntbinding
```

Note however that (as in Example 2) the left-argument to (2015I) specifies that the exported data type of the sizeSource variable is to be Int 32.

## Testing the Data Binding

) LOAD WPFIntro
)CS DataBinding. TextFontSizeCode

| $\square$ | 回 | X |
| :--- | :--- | :--- | dlroW olleH

As in previous examples, when the user changes the text, the new text appears in txtSource.

txtSource
Learn to play the bouzouki!

## Note

It is perhaps worth mentioning that if you want to bind two properties of the same object to two APL variables, it has to be done by writing code as shown in this example, using two separate Binding Source objects. This is because using XAML you may only associate a single Binding Source to an object.

However, this minor restriction is easily surmounted by using an APL namespace as a Binding Source as illustrated in the next Example.

## Example 4

This example uses XAML to specify the user-interface and the main components of the data binding.

## The XAML

The XAML is much the same as in Example 1 and 2 except that it connects two properties Text and FontSize of the same TextBox to two Paths txtSource and sizeSource.

```
<Window
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentation"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Name="Temp"
    Title="Data Binding (Text and FontSize)"
    SizeToContent="WidthandHeight">
    <TextBox Name="txt" Width="350" Margin="5"
        Text="{Binding txtSource,Mode=TwoWay,
            UpdateSourceTrigger=PropertyChanged} "
        FontSize="{Binding sizeSource,Mode=OneWay}"/>
</Window>
```

## The APL Code

The function TextFontSize is shown below.

```
\nabla TextFontSize(txt size);DUSING;win;options
[1] DUSING*'System'
[2] DUSING,*C'System.Windows,
                WPF/PresentationFramework.dll'
[4] win<LoadXAML XAML
[6] src<-DNS''
[7] src.(txtSource sizeSource)<txt size
[8] options&2 2p'txtSource'String'sizeSource'Int32
[10] win.DataContext<options(2015I)'src'
[12] win.Show
    \nabla
```

[3]
[5]
[9]
[11]

Lines [6-7] create a new namespace src containg two variables $t \times t$ Source and sizeSource which are initialised to the arguments of the function.

```
[6] src+ \({ }^{\prime} \mathrm{NS}^{\prime \prime}\)
[7] src.(txtSource sizeSource) ヶtxt size
```

Line [8] creates a local variable named options which will be used as the left argument of 2015I). It is a 2 -column matrix. The first column is a list of the names of the variables which are to be exported by the namespace when used as a Binding Source. The second column specifies their data types.
[8] options $\leftarrow 2$ 2p'txtSource'String'sizeSource'Int 32
Line [10] creates a Binding Source object from the namespace src and a left argument options and assigns it to the DataContext property of the Window win.
[10] win.DataContext+options(2015I)'src'
An alternative would be to assign it to the DataContext property of the TextBox object, but this would require one further line of code to identify it. The reason this works is that the DataContext property of a TextBox (and many other controls) is inherited from its parent Window. This feature allows a single Binding Source namespace to be used to specify data bindings between its component variables and any number of properties of any number of controls in the same Window.

As shown before, the left argument of 2015 I) is optional. Without it, the namespace would export all its variables using default binding types. In this case, because the binding type of sizeSource must be specifed as Int32, it is necessary to use a left argument, which means specifying all the variables involved.

## Testing the Data Binding

) LOAD WPFIntro
)CS DataBinding. TextFontSizeXAML
DB_Text_FontSize_XAML'Hello World' 30

src.(txtSource sizeSource $\leftarrow(\phi t x t$ Source) 18)

As in previous examples, when the user changes the text, the new text appears in txtSource.

src.txtSource
Learn to play the bouzouki!

## Example 5

WPF data binding provides the means to bind controls that display lists of items, such as the ListBox, ListView, and TreeView controls, to collections of data. These controls are all based upon the ItemsControl class. To bind an ItemsControl to a collection object, you use its ItemsSource property.

If the right argument of 2015I names a variable, or a namespace containing a variable, that is a vector other than a simple character vector, it returns a Binding Source object that provides the necessary interfaces to bind the variable as a collection to the ItemSource property of an ItemsControl.

The APL variable will normally contain a vector of character vectors, because most ItemsControl objects deal with collections of strings. However, any APL vector other than a simple character vector will be treated in this way.

This example illustrates binding between a variable containing a vector of character vectors, to the items of a ListBox.

Incidentally, the ItemsSource property overrides the Items collection as a means to specify the content of the ItemsControl. When the ItemsSource property is set, the Items collection becomes read-only and of fixed-size. Note that the ItemsSource property supports OneWay binding by default.

## The XAML

The variable XAML_FilteredList, shown below, contains XAML to specify a Window containing a StackPanel. The StackPanel control is a WPF layout control that organises child controls in a single line, by default vertically. In this example, the StackPanel contains a TextBox and, below it, a WrapPanel, and below that a TextBlock. The WrapPanel is also a layout control that organises its child controls sequentially from left to right. The WrapPanel contains two ListBox controls.

```
<Window
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentat
ion"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Title="Filtered List Example"
    SizeToContent="WidthAndHeight"
    Topmost="true">
    <StackPanel>
            <TextBox Name="filter" Margin="5"
            Text="{Binding Filter,Mode=TwoWay,
                            UpdateSourceTrigger=PropertyChanged}"/>
            <WrapPanel>
                <ListBox Name="all" Width="135" Height="440"
                    Margin="5" ItemsSource="{Binding DyalogNames}"/>
                    <ListBox Name="filtered" Width="135" Height="440"
                        Margin="5" ItemsSource="{Binding FilteredList}"/>
            </WrapPanel>
            <TextBlock Text="Dyalog WPF Demo" Margin="5"/>
    </StackPanel>
</Window>
```

## The Code

$$
\text { } \nabla \text { FilteredList;MySource;win;sink }
$$

[1]
MySource+ZNS' '
[2]
MySource.Filter*''
[4] MySource.FilteredList $+0 \rho c^{\prime \prime}$
[5] MySource.DyalogNames $\leftarrow$ DyalogNames
[6]
[7] win↔LoadXAML XAML_FilteredList
[8] Win.DataContext $<2 \overline{0} 15 I^{\prime}$ MySource'
[9] (win.FindNamec'filter').onTextChanged
'FilteredList_TextChanged'
[10] sink+win.ShowDialog
$\nabla$
Like the previous example, this example uses a namespace My Source containing the bound variables Filter, FilteredList and DyalogNames.

FilteredList[8] creates a Binding Source object and assigns it to the DataContext property of the Window win.
[8] Win.DataContext+2015I'MySource'
The DataContext property is inherited by all child controls, so they all share the same Binding Source. Their different Paths to different values in the Binding Source are specified in the XAML as follows.

The Text property of the TextBox named filter is bound to the variable Filter by the expression Text=" $\{$ Binding Filter, ...

```
<TextBox Name="filter" Margin="5"
    Text="{Binding Filter,Mode=TwoWay,
```

The ItemsSource property of the ListBox named all is bound to the variable DyalogNames by the expression ItemsSource=" \{Binding DyalogNames \} "

```
<ListBox Name="all" Width="135" Height="440"
    Margin="5" ItemsSource="{Binding DyalogNames}"/>
```

Thirdly, the ItemsSource property of the ListBox named filtered is bound to the variable FilteredList by the expression ItemsSource=" $\{$ Binding FilteredList\}"

```
<ListBox Name="filtered" Width="135" Height="440"
    Margin="5" ItemsSource="{Binding FilteredList}"/>
```

## Testing the Data Binding

> FilteredList

If the user types a single character, in this case "e", into the TextBox, this fires a TextChanged event which in turn fires the callback function shown below:
$\nabla$ FilteredList_TextChanged a;hits
[1] hits $\leftarrow$ (cMySource.Filter) $\{v / \alpha \in \omega\}^{*}$ DyalogNames
[2] MySource.FilteredList+hits/DyalogNames
$\nabla$

When the callback runs, the variable MySource.Filter, which is bound to the Text property of the TextBox, will contain "e". The function calculates a mask hits which identifies which members of the variable DyalogNames contain this string. It then assigns that subset to the variable MySource.FilteredList. This is bound to the ItemsSource property of the right-hand ListBox, so the result is as follows:

| \% Filtered List Example - ロ |  |
| :---: | :---: |
| e |  |
| Andy Shiers <br> Fiona Smith <br> Richard Smith <br> Jay Foad <br> Jonathan Manktelow <br> Bjørn Christensen <br> John Scholes <br> Vibeke Ulmann <br> Jason Rivers <br> Liam Flanagan <br> Karen Shaw <br> Pat Buteux <br> John Daintree <br> Brian Becker <br> Roger Hui <br> Morten Kromberg <br> Gitte Christensen <br> Dan Baronet <br> Nicolas Delcros | Andy Shiers <br> Jonathan Manktelow <br> Bjorn Christensen <br> John Scholes <br> Vibeke Ulmann <br> Jason Rivers <br> Karen Shaw <br> Pat Buteux <br> John Daintree <br> Brian Becker <br> Roger Hui <br> Morten Kromberg <br> Gitte Christensen <br> Dan Baronet <br> Nicolas Delcros |
| Dyalog WPF Demo |  |

Similarly, typing "er" into the TexBox reduces the number of hits as shown below:

| Filtered List Example - $\square$ |  | $\times$ |
| :---: | :---: | :---: |
| er |  |  |
| Andy Shiers <br> Fiona Smith <br> Richard Smith <br> Jay Foad <br> Jonathan Manktelow <br> Bjørn Christensen <br> John Scholes <br> Vibeke Ulmann <br> Jason Rivers <br> Liam Flanagan <br> Karen Shaw <br> Pat Buteux <br> John Daintree <br> Brian Becker <br> Roger Hui <br> Morten Kromberg <br> Gitte Christensen <br> Dan Baronet <br> Nicolas Delcros | Andy Shiers Jason Rivers Brian Becker Roger Hui Morten Kromberg |  |
| Dyalog WPF Demo |  |  |

## Example 6

This example illustrates data binding using a vector of .NET objects, in this case DateTime objects.

## The XAML

The XAML shown below, describes a Window containing a StackPanel, inside which is a ListBox.
<Window

```
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentat
ion"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Title="NetObjects (DateTime) Example"
    SizeToContent="WidthAndHeight" >
    <StackPanel>
        <TextBlock Text="Dates of forthcoming Orthodox Easters"
        FontSize="18" Margin="5"/>
            <ListBox Name="EasterDates" Height="100"
            Margin="5" />
    </StackPanel>
</Window>
```

## The APL Code

The function NetObjects is shown below.

```
\nabla NetObjects;DUSING;win;dt
    ZUSING*'System'
    win<LoadXAML XAML
    win.dates\leftarrowwin.FindNamec'EasterDates'
    dt<{DNEW DateTime \omega}"Easter
    win.dates.ItemsSource\leftarrow2015I'dt'
    sink+win.ShowDialog
    \nabla
```

NetObjects[3] uses FindName to obtain a ref to the ListBox (defined in the XAML) named EasterDates:

```
[3] win.dates\leftarrowwin.FindNamec'EasterDates'
```

The global variable Easter contains a vector of 3-element numeric vectors representing the dates of forthcoming Orthodox Easter Sundays.

|  | 个Easter |  |
| :--- | ---: | ---: |
| 2015 | 4 | 12 |
| 2016 | 5 | 1 |
| 2017 | 4 | 16 |
| 2018 | 4 | 8 |
| 2019 | 4 | 28 |
| 2020 | 4 | 19 |
| 2021 | 5 | 2 |
| 2022 | 4 | 24 |
| 2023 | 4 | 16 |
| 2024 | 5 | 5 |

NetObjects[4] creates a vector of DateTime objects from the global variable Easter.
[4] dt<\{DNEW DateTime $\omega$ \}"Easter
Then, NetObjects[5] creates a binding source object from this array and assigns it to the ItemsSource property of the ListBox.

```
[5] win.dates.ItemsSource<2015I'dt'
```

## Testing the Data Binding

```
    )LOAD WPFIntro
    DataBinding.NETObjects.NETObjects

4/8/2018
4/28/2019
4/19/2020

## Example 7

This example illustrates data binding using a vector of namespaces.
Each row in the WPF DataGrid control is represented by an object, and each column as a property of that object. Each row in the DataGrid is bound to an object in the data source, and each column in the data grid is bound to a property of the data object.

| BataGrid Example |  |
| :--- | :--- | :--- |
| Wine |  |
| Chateau Canon-La-Gafferiere | $\$ 105.39$ |
| Chateau Cantenac | $\$ 110.10$ |
| Chateau Cap-Le-Mourlin | $\$ 156.53$ |
| Chateau Cardinal-Villemaurine | $\$ 150.46$ |
| Chateau Cassevert | $\$ 134.56$ |
| Chateau Chapelle-Madeleine | $\$ 184.46$ |
| Chateau Cote-Daugay-ex-Madeleine | $\$ 185.80$ |
| Chateau Coutet | $\$ 199.22$ |
| Chateau Cure-Bon-La-Madeleine | $\$ 133.16$ |
| Chateau Faurie-de-Soutard | $\$ 151.28$ |
| Chateau Fonplegade | $\$ 195.43$ |
| Clos Fourtet | $\$ 189.00$ |
| Chateau Franc-Mayne | $\$ 195.77$ |
| Chateau Franc-Pourret | $\$ 130.77$ |
| Domaine du Grand-Faurie | $\$ 133.13$ |
| Chateau Grand-Mayne | $\$ 156.58$ |
| Chateau Grand-Ponet | $\$ 116.63$ |
| Chateau Grandes Murailles | $\$ 150.82$ |
| Chateau Guadet-Saint-Julien | $\$ 147.74$ |
| Chateau GueyrotHaut-Cadet | $\$ 134.54$ |
| Chateau Haut-Pontet | $\$ 154.69$ |
| Chateau Haut-Simard | $\$ 182.55$ |
| Chateau Haut-Trimoulet | $\$ 153.00$ |

## The XAML

The XAML shown below, describes a Window containing a DockPanel, inside which is a DataGrid.

```
<Window
    xmlns="http://schemas.microsoft.com/winfx/2006/xaml/presentat
ion"
    xmlns:x="http://schemas.microsoft.com/winfx/2006/xaml"
    Title="DataGrid Example" Height="500"
    SizeToContent="Width"
    Topmost="true">
    <DockPanel>
        <DataGrid Name="DG1" ItemsSource="{Binding}"
                AutoGenerateColumns="False" >
                <DataGrid.Columns>
                        <DataGridTextColumn Header="Wine"
                        Binding="{Binding Name}"/>
                            <DataGridTextColumn Header="Price"
                Binding="{Binding Price, StringFormat=C}" />
            </DataGrid.Columns>
            </DataGrid>
    </DockPanel>
</Window>
```

The phrase ItemsSource=" \{Binding \}" states that the content of the DataGrid is bound to a data source, which in this case will be inherited from the DataContext property of the parent Window.

Binding=" $\{$ Binding Name \}" specifies that the contents of the first column are bound to a Path named Name in the data source.

Similarly, Binding="\{Binding Price, StringFormat=C\}" specifies that the Path for the second column is Price (StringFormat=C merely specifies the default currency format).

## The APL Code

The function Grid is shown below.

```
    \nabla Grid;QUSING;MySource;win
[1] UUSING<'System'
[2] winelist-पNS"(oWines)pc''
[3] winelist.Name<Wines
[4] Winelist.Price*0.01\times10000+?(pWines)p10000
[6] win\leftarrowLoadXAML XAML
[7] win.DataContext<2015I'winelist'
[8] win.Show
    \nabla
```

[5]

The global variable Wines contains a vector of character vectors, each of which is the name of a wine. Grid[2-4] creates winelist, a vector of namespaces, of the same length, each of which contains two variables c Name and Price.

## Testing the Data Binding

) LOAD WPFIntro
)CS DataBinding.DataGrid Grid

| WataGrid Example | $\square$ 回 $\times$ |  |
| :---: | :---: | :---: |
| Wine | Price |  |
| Chateau Canon-La-Gafferiere | \$105.39 | * |
| Chateau Cantenac | \$110.10 |  |
| Chateau Cap-Le-Mourlin | \$156.53 |  |
| Chateau Cardinal-Villemaurine | \$150.46 |  |
| Chateau Cassevert | \$134.56 |  |
| Chateau Chapelle-Madeleine | \$184.46 |  |
| Chateau Cote-Daugay-ex-Madeleine | \$185.80 |  |
| Chateau Coutet | \$199.22 | 三 |
| Chateau Cure-Bon-La-Madeleine | \$133.16 |  |
| Chateau Faurie-de-Soutard | \$151.28 |  |
| Chateau Fonplegade | \$195.43 |  |
| Clos Fourtet | \$189.00 |  |
| Chateau Franc-Mayne | \$195.77 |  |
| Chateau Franc-Pourret | \$130.77 |  |
| Domaine du Grand-Faurie | \$133.13 |  |
| Chateau Grand-Mayne | \$156.58 |  |
| Chateau Grand-Ponet | \$116.63 |  |
| Chateau Grandes Murailles | \$150.82 |  |
| Chateau Guadet-Saint-Julien | \$147.74 |  |
| Chateau GueyrotHaut-Cadet | \$134.54 |  |
| Chateau Haut-Pontet | \$154.69 |  |
| Chateau Haut-Simard | \$182.55 |  |
| Chateau Haut-Trimoulet | \$153.00 | $\checkmark$ |

Let's round the prices to the nearest $\$ 5$.

$$
\text { winelist.Price } \leftarrow 5 \times \text { L } 0.5+\text { winelist.Price } \div 5
$$

| BataGrid Example |  |
| :--- | :--- | :--- |
| Wine | Price |
| Chateau Canon-La-Gafferiere | $\$ 105.00$ |
| Chateau Cantenac | $\$ 110.00$ |
| Chateau Cap-Le-Mourlin | $\$ 155.00$ |
| Chateau Cardinal-Villemaurine | $\$ 150.00$ |
| Chateau Cassevert | $\$ 135.00$ |
| Chateau Chapelle-Madeleine | $\$ 185.00$ |
| Chateau Cote-Daugay-ex-Madeleine | $\$ 185.00$ |
| Chateau Coutet | $\$ 200.00$ |
| Chateau Cure-Bon-La-Madeleine | $\$ 135.00$ |
| Chateau Faurie-de-Soutard | $\$ 150.00$ |
| Chateau Fonplegade | $\$ 195.00$ |
| Clos Fourtet | $\$ 190.00$ |
| Chateau Franc-Mayne | $\$ 195.00$ |
| Chateau Franc-Pourret | $\$ 130.00$ |
| Domaine du Grand-Faurie | $\$ 135.00$ |
| Chateau Grand-Mayne | $\$ 155.00$ |
| Chateau Grand-Ponet | $\$ 115.00$ |
| Chateau Grandes Murailles | $\$ 150.00$ |
| Chateau Guadet-Saint-Julien | $\$ 150.00$ |
| Chateau GueyrotHaut-Cadet | $\$ 135.00$ |
| Chateau Haut-Pontet | $\$ 155.00$ |
| Chateau Haut-Simard | $\$ 185.00$ |
| Chateau Haut-Trimoulet | $\$ 155.00$ |

## Syncfusion Libraries

Under a licensing agreement with Syncfusion, Dyalog includes the Syncfusion library of WPF controls. These may be used by Dyalog APL users to develop applications, and may be distributed with Dyalog APL run-time applications.

The Syncfusion libraries comprise a set of .NET assemblies which are supplied in the Syncfusion/4.5 sub-directory of the main Dyalog APL installation directory (for example: c:|Program Files $\backslash$ Dyalog $\backslash$ Dyalog APL-64 14.0 UnicodelSyncfusion\4.5.

## Requirements

To use the Syncfusion libraries you must be using Microsoft .NET Version 4.5. See User's Guide: Configuration Dialog:.NET Framework Tab.

In addition, to use the controls contained in these assemblies it is necessary to perform one or both of the following steps.

## Using XAML

If using XAML, the XAML must include the appropriate xmlns statements that specify where the Syncfusion controls are to be found. For example:

```
xmlns:syncfusion="clr-namespace:Syncfusion.Windows.Gauge;
    assembly=Syncfusion.Gauge.WPF"
```

The above statement defines the prefix syncfusion to mean the specified Syncfusion namespace and assembly that contains the various Gauge controls. When the prefix syncfusion is subsequently used in front of a control in the XAML, the system knows where to find it. For example:

```
<syncfusion:CircularGauge Name="fahrenheit" Margin="10">
```

## ZUSING

In common with all .NET types, when a Syncfusion control is loaded using XAML or using DNEW it is essential that the current value of पUS INGidentifies the .NET namespace and assembly in which the control will be found. For example:

$$
\begin{aligned}
& \text { QUSING, } \leftarrow c ' S y n c f u s i o n . ~ W i n d o w s . G a u g e, ~ \\
& \text { Syncfusion/4.5/Syncfusion.Gauge.WPF.dll' }
\end{aligned}
$$

This statement tells APL to search the .NET namespace named Syncfusion.Windows.Gauge, which is located in the assembly file whose path (relative to the Dyalog installation directory) is
Syncfusion/4.5/Syncfusion.Gauge.WPF.dll.

## Syncfusion Circular Gauge Example

## The XAML

Like most Syncfusion controls, the CircularGauge is made up of a complex structure of objects, and the XAML (see variable XAML_SF) is too extensive to describe in detail herein. It was created from the sample XAML from the Syncfusion documentation for this control entitled Essential Gauge for WPF, which may be downloaded from http://help.syncfusion.com/wpf/gauge.
The key statements in the XAML are as follows:

```
xmlns:syncfusion="clr-namespace:Syncfusion.Windows.Gauge;
    assembly=Syncfusion.Gauge.WPF"
```

The above statement defines the prefix syncfusion to mean the specified Syncfusion namespace and assembly. When the prefix syncfusion is subsequently used in front of a control in the XAML, the system knows where to find it.

The next two statements define CircularPointer controls (the needles on the gauges); one for the Fahrenheit gauge (named $f$ pointer) and one for the Centigrade gauge (named $c \_$pointer).

```
<syncfusion:CircularPointer Name="f_pointer" BorderWidth="0.3"
    PointerLength="100" PointerPlacement="Inside" PointerWidth="20"
    Value="32"/>
<syncfusion:CircularPointer Name="c_pointer" BorderWidth="0.3"
    PointerLength="100" PointerPlacement="Inside" PointerWidth="20"
    Value="0"/
```

## The APL Code

The following functions were used to produce the example illustrated above. The main function is SF_TC_XAML.

```
\nabla SF_TC_XAML;DUSING;win;f_pointer;c_pointer;sink
```

[1]

```
[2] win<LoadXAML XAML_SF
```

[3]
[4] f_pointer*win.FindNamec'f_pointer'
[5] c_pointer*win.FindNamec'c_pointer'
[6]
[7] f_pointer.onMouseEnter*'MouseEnter'
[8] c_pointer.onMouseEnter*'MouseEnter'
[9]
[10] sink↔win.ShowDialog
$\nabla$

After creating the Window from the text in XAML_SF, the function SF_TC_XAML obtains refs to the two CircularPointer controls named $f$ pointer (in the Fahrenheit gauge) and $c$ pointer (in the Centrigrade gauge). It then attaches the MouseEnter callback to each of these objects.

```
    \nabla MouseEnter(this ev);ptrs
[1] ptrs&f_pointer c_pointer
[2] ptrs.onValueChanged\leftarrow(ptrs\imaththis)\phi0 'TempChanged'
\nabla
```

In this example, the user grabs one of the gauge needles and moves it around the face of the gauge. When the user moves the mouse into one of these needles, the MouseEnter callback fires. The function MouseEnter receives the CircularPointer object that generated the event this as the first item in its argument.

The code simply attaches the callback function TempChanged to th is, and disables any callback on the other CircularPointer object.

Note that if both CircularPointer objects had callbacks on TempChanged at the same time, the system would enter a callback loop.

```
    \nabla TempChanged(obj ev)
[1] :Select obj
[2] :Case f_pointer
[3] c_pointer.Value\leftarrow(obj.Value-32) }\times5\div
[4] :Case c_pointer
[5] f_pointer.Value\leftarrow <22+obj.Value % 5 %9
[6] :EndSelect
    \nabla
```

The LoadXAML function used in this example is subtly different from previous examples.

```
    \nabla win<LoadXAML xaml;DUSING;str;xml
[1] UUSING*'System.IO'
[2] ZUSING,*c'System.Windows.Markup'
[3] DUSING,*'System.Xml,system.xml.dll'
[4] DUSING,*C'System.Windows.Controls,
    WPF/PresentationFramework.dll'
[5] [USING,*'Syncfusion.Windows.Gauge,
        Syncfusion/4.5/Syncfusion.Gauge.WPF.dll'
[6] str-पNEW StringReader(cxaml)
[7] xml-पNEW XmlTextReader str
[8] win<XamlReader.Load xml
\nabla
```

In particular, it contains the all-important statement:

```
[5] [USING,*c'Syncfusion.Windows.Gauge,
    Syncfusion/4.5/Syncfusion.Gauge.WPF.dll'
```

This statement tells APL to search the .NET namespace named
Syncfusion.Windows.Gauge, which is located in the assembly file whose path (relative to the Dyalog installation directory) is
Syncfusion/4.5/Syncfusion.Gauge.WPF.dll.

## Chapter 9:

## UNIX Specific Features

## Summary

This section summarises the UNIX specific changes in Dyalog APL Version 14.0.

- Previous versions of Dyalog APL for UNIX included the Dyalog APL for UNIX Installation and User Guide; in version 14.0 this has been split into the Dyalog APL for UNIX Installation and Configuration Guide and the Dyalog APL for UNIX User Guide
- The environment variable SKIPBLANKLINES is used to control whether blank lines and comment-only lines are skipped when tracing. If SKIPBLANKLINES $=0$ then the behaviour in previous versions is retained
- The keystroke CMD-a forces comment alignment
- All shared libraries are now located in \$DYALOG/lib
- In preparation for RIDE, ride*.so and lbar.xml are included in the release, and the mapl script has support for enabling RIDE
- To cater for various terminal windows, translate tables xterm-256, screen and screen- 256 have been added
- 685I has been removed; should APL terminate, both an aplcore and a core file will be generated, removing the need for this functionality
- The function geterrno has been added to dyalog.so; be aware that the error number returned may have been generated subsequently to the original error condition
- The buildse workspace is now included with UNIX releases; this allows the user to recreate their default session file
- The Key character cannot be entered directly at present (May 2014). See the Dyalog APL for UNLX Installation and User Guide for more information.
- From 14.0.22176 onwards, it is possible to close all Editor and Tracer windows using 2023I. This mimics the Close all Windows menuitem in versions of Dyalog for Windows.

[^0]:    ${ }^{1}$ This interface is used by Dyalog to notify a data consumer when the contents of a variable, that is data bound as a list of items, changes.

[^1]:    ${ }^{1}$ The symbol 目 is not available in Classic Edition，and the Key operator is instead represented by ［U2338

[^2]:    ${ }^{1}$ Mono is an open source implementation of Microsoft's .NET Framework. For more information, see www.mono-project.com.

[^3]:    ${ }^{1}$ The symbol 目 is not available in Classic Edition，and the Key operator is instead represented by ［U2338

[^4]:    ${ }^{1}$ The symbol $\because$ is not available in Classic Edition, and the Rank operator is instead represented by DU2364

[^5]:    ${ }^{1}$ This element sets the span of the file which in earlier Versions of Dyalog APL could be 32 or 64. Small-span (32-bit) component files may no longer be created and this element is retained only for backwards compatibility of code.

[^6]:    ${ }^{1}$ http://www.w3.org/TR/2008/REC-xml-20081126/

[^7]:    ${ }^{1}$ The term memory here means virtual memory which includes memory mapped to disk.

[^8]:    ${ }^{1}$ It is beyond the scope of this document to fully explain the concepts of WPF data binding. See Microsoft Developer Network, Data Binding Overview.

[^9]:    ${ }^{1}$ This function may remain as an i-beam or be replaced by one or more system functions in a future Version of Dyalog APL.

[^10]:    ${ }^{1}$ A ScrollBar is not the ideal choice of control for this type of user interation, but this example is designed to look and behave like the original Dyalog GUI example, which was written for the original version of Dyalog APL for Windows.

[^11]:    ${ }^{1}$ This is because its binding type (the exported type of the data bound variable) is stored in the workspace along with its value, and the binding type (were it to be incorrect) may not be changed once it has been established.

[^12]:    ${ }^{1}$ Binding objects are implicit in all binding operations, but are created declaratively when using XAML.
